SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

**Table 45-11. Bosch CAN 2.0B standard compliant bit time segment settings**

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

**Note**

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

**Figure 45-11. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0**

where:

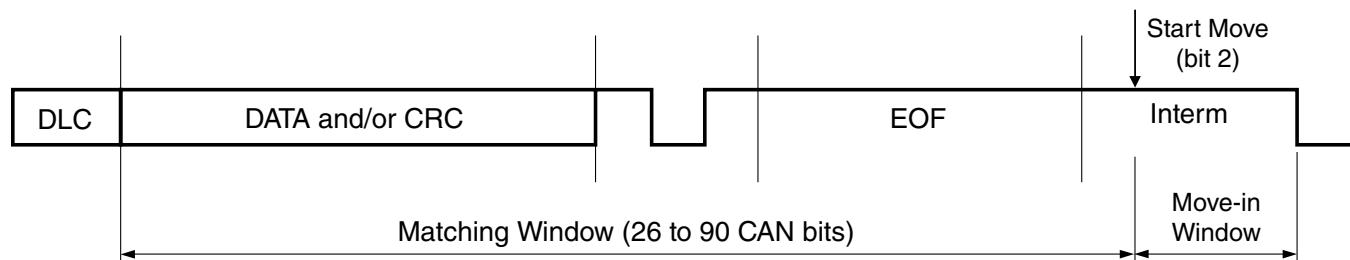

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f<sub>CANCLK</sub> is the Protocol Engine (PE) Clock (see [Figure 45-6](#)), in Hz.
- f<sub>SYS</sub> is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.
- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRESDIV is the value in CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) and also to the CAN FD Bit Timing register (FDCBT).

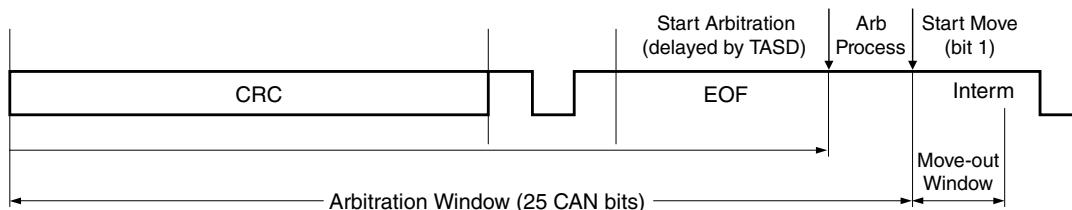

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

### 45.3.9.8 Arbitration and matching timing

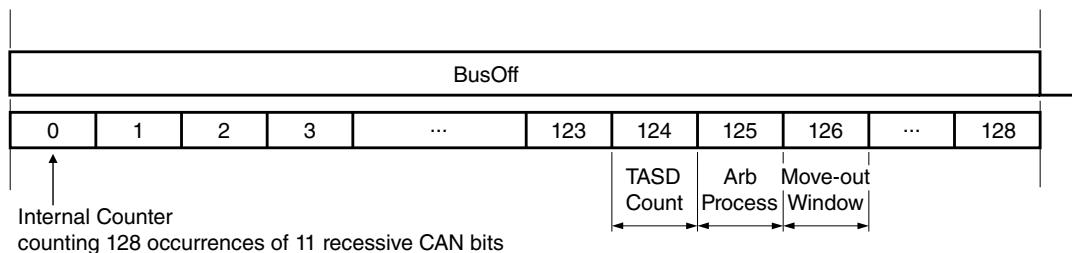

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 45-12. Matching and move-in time windows**

**Figure 45-13. Arbitration and move-out time windows**

**Figure 45-14. Arbitration at the end of bus off and move-out time windows**

#### NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

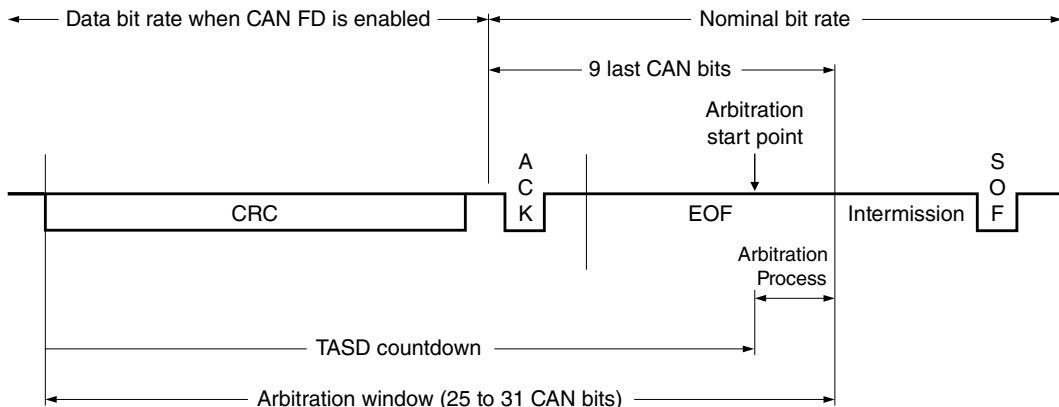

### 45.3.9.9 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see [Arbitration process](#)). If the arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

**Figure 45-15. Optimal Tx Arbitration start point**

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and  $(\text{MAXMB} + 1) \leq \text{NMB}_{\text{END}}$

$$\text{TASD} = 31 - \frac{2 * (\text{MAXMB} + 1) + 4}{\text{CPCB}_N}$$

For CAN FD frames and  $(\text{MAXMB} + 1) > \text{NMB}_{\text{END}}$

$$\text{TASD} = 22 - \frac{2 * (\text{MAXMB} + 1) - \text{NMB}_{\text{END}}}{\text{CPCB}_F}$$

For non-FD frames

$$\text{TASD} = 25 - \frac{2 * (\text{MAXMB} + 1) + 4}{\text{CPCB}}$$

**Figure 45-16. Optimal value for TASD**

where:

$$\text{NMB}_{\text{END}} = \frac{(9 * \text{CPCB}_N) - 4}{2}$$

$$\text{BITRATE}_N = \left( \frac{f_{\text{CANCLK}}}{[1 + (\text{EPSEG1} + 1) + (\text{EPSEG2} + 1) + (\text{EPROPSEG} + 1)] \times (\text{EPRESDIV} + 1)} \right)$$

$$\text{BITRATE}_F = \left( \frac{f_{\text{CANCLK}}}{[1 + (\text{FPSEG1} + 1) + (\text{FPSEG2} + 1) + \text{FPROPSEG}] \times (\text{FPRESDIV} + 1)} \right)$$

$$\text{CPCB}_N = \frac{f_{\text{SYS}}}{\text{BITRATE}_N}$$

$$\text{CPCB}_F = \frac{f_{\text{SYS}}}{\text{BITRATE}_F}$$

$$\text{CPCB} = \text{CPCB}_N$$

**Figure 45-17. Variables used in TASD calculation**

- MAXMB is the value in CTRL1[MAXMB].
- NMB<sub>END</sub> is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- BITRATE<sub>N</sub> is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- BITRATE<sub>F</sub> is the CAN bit rate in bits per second calculated by the data CAN bit time variables.

## Functional description

- $CPCB_N$  is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$  is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- $CPCB$  is the number of peripheral clocks per CAN bit for non-FD frames.
- $f_{CANCLK}$  is the oscillator clock, in Hz.
- $f_{SYS}$  is the peripheral clock, in Hz.
- $EPSEG1$  is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- $EPSEG2$  is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- $EPROPSEG$  is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- $EPRESDIV$  is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- $FPSEG1$  is the value in FDCBT[FPSEG1].
- $FPSEG2$  is the value in FDCBT[FPSEG2].
- $FPROPSEG$  is the value in FDCBT[FPROPSEG].
- $FPRESDIV$  is the value in FDCBT[FPRESDIV].

See also [Protocol timing](#) for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 45-12. TASD values:**

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 45-13. TASD values:**

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67

*Table continues on the next page...*

**Table 45-13. TASD values: (continued)**

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
54	22	5.0
64	21	3.33

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 45-14. TASD values:**

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33

## 45.3.10 Clocks

The following table describes the clock sources for FlexCAN. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

**Table 45-15. FlexCAN clocks**

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_chi	Control Host Interface (CHI) clock
ipg_clk_pe	Protocol Engine (PE) clock
ipg_clk_pe_nogate	Protocol Engine clock (no gating)
ipg_clk_s	Peripheral access clock

### 45.3.10.1 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

### NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

**Table 45-16. Minimum number of peripheral clocks per CAN bit for Classical CAN format**

Number of mailboxes	Value of MCR[RFEN]	Minimum number of peripheral clocks per CAN bit
16	0	16
32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT). The time quantum ( $T_q$ ) is defined in [Protocol timing](#). The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{\text{SYS}}}{\text{NomBitRate}}$$

**Figure 45-18. Number of peripheral clocks per nominal CAN bit**

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

**Table 45-17. Number of fast CAN bits in a CAN FD frame**

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \times \text{MaxNumOfMb}) + 64 - (9 \times \text{NumClkNomBit})}{\text{NumOfFastBits}}$$

**Figure 45-19. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process**

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$\text{MinNumClkFastBit}_B = 3 \times \left( 1 + \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \right)$$

**Figure 45-20. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$\text{MinNumClkFastBit} = \text{Maximum}(\text{MinNumClkFastBit}_A, \text{MinNumClkFastBit}_B)$$

**Figure 45-21. Minimum number of peripheral clocks per fast CAN bit**

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$\text{DataBitrate}_{\text{MAX}} = \frac{f_{\text{CANCLK}}}{\text{ROUNDUP}\left(\frac{\text{MinNumClkFastBit} \times f_{\text{CANCLK}}}{f_{\text{SYS}}}\right)}$$

**Figure 45-22. Maximum achievable baud rate for data phase**

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$\text{NumClkNomBit} = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

**Figure 45-23. Calculation example for number of peripheral clocks per nominal CAN bit**

2. The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

**Figure 45-24. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process**

$$\text{MinNumClkFastBit}_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

**Figure 45-25. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

$$\text{MinNumClkFastBit} = \text{Maximum}(5.06, 6.75) = 6.75$$

**Figure 45-26. Calculation example for number of peripheral clocks per fast CAN bit**

4. The maximum CAN bit rate in the data phase can finally be found.

$$\text{DataBitRate}_{\text{MAX}} = \frac{40 \times 10^6}{\text{ROUNDUP}\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667 \text{ Mbps}$$

**Figure 45-27. Calculation example for maximum achievable baud rate**

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

**Table 45-18. Maximum CAN bit rate in data phase on CAN FD frames**

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667

*Table continues on the next page...*

**Table 45-18. Maximum CAN bit rate in data phase on CAN FD frames (continued)**

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

### 45.3.11 Reset

You can reset FlexCAN in the following ways:

1. Chip level [hard reset](#), which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See [Table 45-21](#) to see what registers are affected by [soft reset](#).
3. Chip level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

## 45.3.12 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Wake Up, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of [Interrupt Flags 1 Register \(IFLAG1\)](#) for more information.

If both Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

### CAUTION

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done

- Error
- Error Fast
- Wake Up
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register; the Wake-Up interrupt mask bit is located in MCR.

### 45.3.13 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in [Table 45-21](#) in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  - a. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  - b. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

- c. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

**Table 45-19. Access permissions**

Reserved space (used) <sup>1</sup>	bus error						
Reserved space (empty) <sup>1</sup>	bus error						

1. Access in low power is only possible if RAM\_clk and ipg\_clk are enabled.
2. If MCR[RFEN] = 1, see FIFO access rules below.
3. Write operation has no effect.

## 45.4 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 45-20. FlexCAN signal descriptions**

Signal	Description	I/O
CAN Rx	CAN receive pin	Input
CAN Tx	CAN transmit pin	Output

## 45.4.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 45.4.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 45.5 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

### 45.5.1 FlexCAN initialization sequence

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see [Freeze mode](#)). Note that the module needs to be initialized after every reset.

The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
  - a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
  - b. Enable the warning interrupts by setting WRNEN.
  - c. If required, disable frame self reception by setting SRXDIS.
  - d. Enable the Rx FIFO by setting RFEN.
  - e. If Rx FIFO is enabled and DMA is required, set DMA.
  - f. Enable the abort mechanism by setting AEN.
  - g. Enable the local priority feature by setting LPPIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
  - a. Determine the bit timing parameters: PROPSSEG, PSEG1, PSEG2, and RJW.
  - b. Optionally determine the bit timing parameters: EPROPSSEG, EPSEG1, EPSEG2, and ERJW.
  - c. Determine the CAN FD bit timing parameters: FPROPSSEG, FPSEG1, FPSEG2, and FRJW.
  - d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
  - e. Determine the CAN FD bit rate by programming the FPRESDIV field.

- f. Determine the internal arbitration mode (LBUF).
3. Initialize the message buffers.
  - a. The control and status word of all message buffers must be initialized.
  - b. If Rx FIFO was enabled, the ID filter table must be initialized.
  - c. Other entries in each message buffer should be initialized as required.
4. Initialize the Rx Individual Mask registers (RXIMRn).
5. Set required interrupt mask bits in
  - IMASK registers (for all MB interrupts)
  - MCR register (for Wake-Up interrupt)
  - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
6. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

## 45.6 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 45.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic . The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of [Table 45-21](#).

#### NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

**Table 45-21. Register access and reset information**

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 Register (CTRL1)	S/U	Yes	No

*Table continues on the next page...*

**Table 45-21. Register access and reset information (continued)**

Register	Access type	Affected by hard reset	Affected by soft reset
Free Running Timer Register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask Register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask Register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask Register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 Register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 Register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 Register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 Register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask Register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
CAN Bit Timing Register (CBT)	S/U	Yes	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
CAN FD Control Register (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing Register (FDCBT)	S/U	Yes	No
CAN FD CRC Register (FDCRC)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

## 45.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–47Fh allocates the sixty-four 128-bit message buffers (MBs).

The memory maps for the message buffers are in [FlexCAN message buffer memory map](#).

## 45.6.2.1 CAN memory map

FLEXCAN3 base address: 401D\_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	5980_000Fh
4h	Control 1 Register (CTRL1)	32	RW	0000_0000h
8h	Free Running Timer (TIMER)	32	RW	0000_0000h
10h	Rx Mailboxes Global Mask Register (RXMGMASK)	32	RW	<a href="#">Table 45-21</a>
14h	Rx 14 Mask Register (RX14MASK)	32	RW	<a href="#">Table 45-21</a>
18h	Rx 15 Mask Register (RX15MASK)	32	RW	<a href="#">Table 45-21</a>
1Ch	Error Counter (ECR)	32	RW	0000_0000h
20h	Error and Status 1 Register (ESR1)	32	R2C	0000_0000h
24h	Interrupt Masks 2 Register (IMASK2)	32	RW	0000_0000h
28h	Interrupt Masks 1 Register (IMASK1)	32	RW	0000_0000h
2Ch	Interrupt Flags 2 Register (IFLAG2)	32	W1C	0000_0000h
30h	Interrupt Flags 1 Register (IFLAG1)	32	W1C	0000_0000h
34h	Control 2 Register (CTRL2)	32	RW	0080_0000h
38h	Error and Status 2 Register (ESR2)	32	RO	0000_0000h
44h	CRC Register (CRCR)	32	RO	0000_0000h
48h	Rx FIFO Global Mask Register (RXFGMASK)	32	RW	<a href="#">Table 45-24</a>
4Ch	Rx FIFO Information Register (RXFIR)	32	RO	<a href="#">Table 45-24</a>
50h	CAN Bit Timing Register (CBT)	32	RW	0000_0000h
880h - 97Ch	Rx Individual Mask Registers (RXIMR0 - RXIMR63)	32	RW	<a href="#">Table 45-24</a>

### 45.6.2.2.4 Fields

Field	Function
31 MDIS	Module Disable  This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset.  0b - Enable the FlexCAN module. 1b - Disable the FlexCAN module.
30 FRZ	Freeze Enable  The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.  0b - Not enabled to enter Freeze mode. 1b - Enabled to enter Freeze mode.
29 RFEN	Rx FIFO Enable  This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 45-16</a> . This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.  <b>NOTE:</b> This bit cannot be set when CAN FD operation is enabled (see FDEN bit). 0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.
28	Halt FlexCAN

Table continues on the next page...

## Memory map/register definition

Field	Function
HALT	<p>Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode.</p> <p>0b - No Freeze mode request. 1b - Enters Freeze mode if the FRZ bit is asserted.</p>
27 NOTRDY	<p>FlexCAN Not Ready</p> <p>This read-only bit indicates that FlexCAN is either in Disable mode, Doze mode, Stop mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset.</p> <p>0b - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode. 1b - FlexCAN module is either in Disable mode, Doze mode, Stop mode, or Freeze mode.</p>
26 WAKMSK	<p>Wake Up Interrupt Mask</p> <p>This bit enables the Wake Up interrupt generation under Self Wake Up mechanism.</p> <p>0b - Wake Up interrupt is disabled. 1b - Wake Up interrupt is enabled.</p>
25 SOFTRST	<p>Soft Reset</p> <p>When SOFTRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers.</p> <p>SOFTRST can be asserted directly by the CPU when it writes to the MCR register, but it is also asserted when global soft reset is requested at chip level. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.</p> <p>Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset.</p> <p>0b - No reset request. 1b - Resets the registers affected by soft reset.</p>
24 FRZACK	<p>Freeze Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See <a href="#">Freeze mode</a>. This bit is not affected by soft reset.</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see <a href="#">Protocol timing</a>).</p> <p>0b - FlexCAN not in Freeze mode, prescaler running. 1b - FlexCAN in Freeze mode, prescaler stopped.</p>
23 SUPV	<p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of <a href="#">Table 45-21</a>. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1b - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.</p>
22 SLFWAK	<p>Self Wake Up</p> <p>This bit enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wakeup event, that is, a recessive-to-dominant transition.</p>

Table continues on the next page...

Field	Function
	<p>If a wakeup event is detected during Doze mode, FlexCAN requests to resume its clocks and, if enabled to do so, generates a Wake Up interrupt to the CPU.</p> <p>If a wakeup event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks.</p> <p>When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware.</p> <p>0b - FlexCAN Self Wake Up feature is disabled. 1b - FlexCAN Self Wake Up feature is enabled.</p>
21 WRNEN	<p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.</p> <p>0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>
20 LPMACK	<p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset.</p> <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see <a href="#">Protocol timing</a>).</p> <p>0b - FlexCAN is not in a low-power mode. 1b - FlexCAN is in a low-power mode.</p>
19 WAKSRC	<p>Wake Up Source</p> <p>This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus. 1b - FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.</p>
18 DOZE	<p>Doze Mode Enable</p> <p>This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level. This bit is automatically reset when FlexCAN wakes up from Doze mode upon detecting activity on the CAN bus (self wakeup enabled).</p> <p>0b - FlexCAN is not enabled to enter low-power mode when Doze mode is requested. 1b - FlexCAN is enabled to enter low-power mode when Doze mode is requested.</p>
17 SRXDIS	<p>Self Reception Disable</p> <p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - Self-reception enabled. 1b - Self-reception disabled.</p>
16 IRMQ	<p>Individual Rx Masking And Queue Enable</p> <p>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p>

Table continues on the next page...

## Memory map/register definition

Field	Function
	0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1b - Individual Rx masking and queue feature are enabled.
15 DMA	DMA Enable  DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, so consequently MCR[RFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes.  0b - DMA feature for RX FIFO disabled. 1b - DMA feature for RX FIFO enabled.
14 —	Reserved
13 LPPIOEN	Local Priority Enable  This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  0b - Local Priority disabled. 1b - Local Priority enabled.
12 AEN	Abort Enable  When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  <b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see <a href="#">Transmission abort mechanism</a> ) must be used for updating mailboxes configured for transmission. <b>CAUTION:</b> Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted. 0b - Abort disabled. 1b - Abort enabled.
11 FDEN	CAN FD operation enable  This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only.  <b>NOTE:</b> FlexCAN is able to transmit FD frame format according to ISO 11898-1.  <b>NOTE:</b> The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format. 1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.
10 —	Reserved
9-8 IDAM	ID Acceptance Mode  This 2-bit field identifies the format of the Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See <a href="#">Rx FIFO structure</a> . This field can be written only in Freeze mode because it is blocked by hardware in other modes.  00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element.

*Table continues on the next page...*

Field	Function
	11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	<p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in <a href="#">FlexCAN memory partition for CAN FD</a>.</p> <p>Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 45-16</a>.</p>

### 45.6.2.3 Control 1 Register (CTRL1)

#### 45.6.2.3.1 Offset

Register	Offset
CTRL1	4h

#### 45.6.2.3.2 Function

This Register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

#### NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

The contents of this register are not affected by soft reset.

**45.6.2.3.3 Diagram**

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**45.6.2.3.4 Fields**

Field	Function
31-24 PRESDIV	Prescaler Division Factor  This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Sclock frequency = PE clock frequency / (PRESDIV + 1).
23-22 RJW	Resync Jump Width  This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1  This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  <a href="#">Phase Buffer Segment 1</a> = (PSEG1 + 1) × Time-Quanta.
18-16 PSEG2	Phase Segment 2

Table continues on the next page...

Field	Function
	This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Interrupt Mask  This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Bus Off interrupt disabled. 1b - Bus Off interrupt enabled.
14 ERRMSK	Error Interrupt Mask  This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Error interrupt disabled. 1b - Error interrupt enabled.
13 —	Reserved  <b>NOTE:</b> This field is writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loop Back Mode  This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node.  In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  <b>NOTE:</b> In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message. <b>NOTE:</b> FDCTRL[TDCEN] must be disabled when LPB is asserted. 0b - Loop Back disabled. 1b - Loop Back enabled.
11 TWRNMSK	Tx Warning Interrupt Mask  This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted. 0b - Tx Warning interrupt disabled. 1b - Tx Warning interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask  This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0b - Rx Warning interrupt disabled. 1b - Rx Warning interrupt enabled.
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling  This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes.

*Table continues on the next page...*

## Memory map/register definition

Field	Function
	<p><b>NOTE:</b> For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]). This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1).</p> <p>0b - Just one sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.</p>
6 BOFFREC	<p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p><b>NOTE:</b> See Bus off in the CAN Protocol standard (ISO 11898-1) for details.</p> <p>0b - Automatic recovering from Bus Off state enabled. 1b - Automatic recovering from Bus Off state disabled.</p>
5 TSYN	<p>Timer Sync</p> <p>This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message, that is, global network time. If MCR[RFEN] is set (Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0b - Timer sync feature disabled 1b - Timer sync feature enabled</p>
4 LBUF	<p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRIOEN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.</p> <p>0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.</p>
3 LOM	<p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message.</p> <p>Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge.</p> <p>This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.</p>
2-0 PROPSEG	<p>Propagation Segment</p> <p>This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Propagation segment time = (PROPSEG + 1) × time-quanta.</p>

Field	Function
	Time-quantum = one Sclock period.

## 45.6.2.4 Free Running Timer (TIMER)

### 45.6.2.4.1 Offset

Register	Offset
TIMER	8h

### 45.6.2.4.2 Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER\_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER\_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see [Mailbox lock mechanism](#)).

## 45.6.2.5 Rx Mailboxes Global Mask Register (RXMGMASK)

### 45.6.2.5.1 Offset

Register	Offset
RXMGMASK	10h

### 45.6.2.5.2 Function

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).

## Memory map/register definition

2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

### 45.6.2.6 Rx 14 Mask Register (RX14MASK)

#### 45.6.2.6.1 Offset

Register	Offset
RX14MASK	14h

#### 45.6.2.6.2 Function

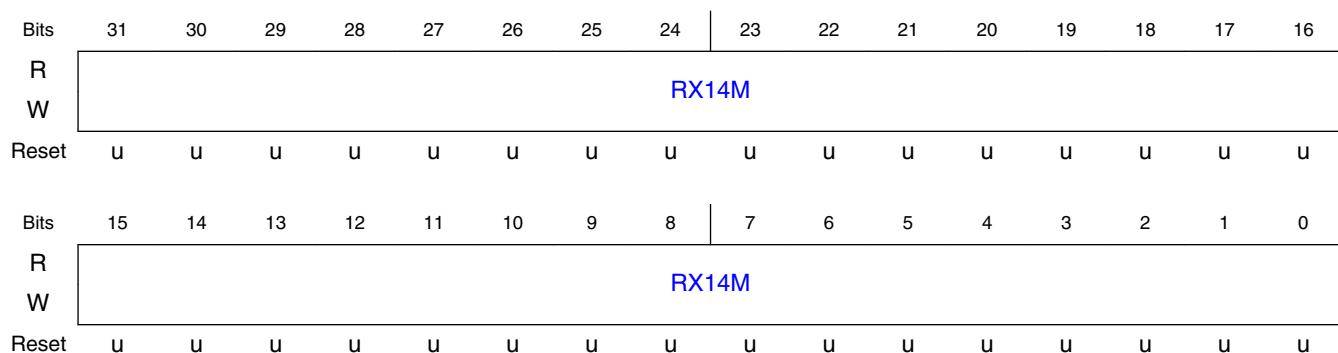

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.

This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

#### 45.6.2.6.3 Diagram

#### 45.6.2.6.4 Fields

Field	Function
31-0	Rx Buffer 14 Mask Bits
RX14M	Each mask bit masks the corresponding mailbox 14 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register.

Field	Function
	0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

## 45.6.2.7 Rx 15 Mask Register (RX15MASK)

### 45.6.2.7.1 Offset

Register	Offset
RX15MASK	18h

### 45.6.2.7.2 Function

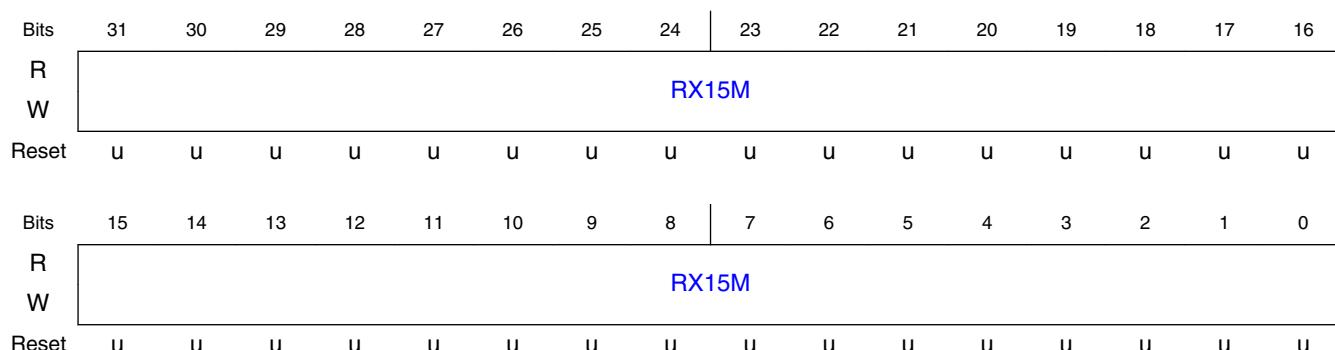

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of message buffer 15.

This register can be programmed only when the module is in Freeze mode because it is blocked by hardware in other modes.

### 45.6.2.7.3 Diagram

## Memory map/register definition

Field	Function
RX15M	Each mask bit masks the corresponding mailbox 15 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

## 45.6.2.8 Error Counter (ECR)

### 45.6.2.8.1 Offset

Register	Offset
ECR	1Ch

### 45.6.2.8.2 Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT\_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT\_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT\_FAST and RXERRCNT\_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT\_FAST and RXERRCNT\_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.

- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT\_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.
- TXERRCNT\_FAST and RXERRCNT\_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

### NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

### 45.6.2.8.4 Fields

Field	Function
31-24	Receive Error Counter for fast bits
RXERRCNT_FAST	Receive error counter for errors detected in the data phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
23-16	Transmit Error Counter for fast bits
TXERRCNT_FAST	Transmit error counter for errors detected in the data phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
15-8	Receive Error Counter
RXERRCNT	Receive error counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
7-0	Transmit Error Counter
TXERRCNT	Transmit error counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

## 45.6.2.9 Error and Status 1 Register (ESR1)

### 45.6.2.9.1 Offset

Register	Offset
ESR1	20h

### 45.6.2.9.2 Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

#### NOTE

Reading Host can clear these field.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR\_FAST
  - BIT0ERR\_FAST
  - CRCERR\_FAST
  - FRMERR\_FAST
  - STFERR\_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT\_FAST
- WAKINT
- TWRNINT
- RWRNINT

## Memory map/register definition

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR\_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT\_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR\_OVR bit is set to indicate that errors from different frames have accumulated.

**Table 45-22. Can bus status**

SYNCH		IDLE		TX		RX		FlexCAN state	
0		0		0		0		Not synchronized to CAN bus	
1		1		x		x		Idle	
1		0		1		0		Transmitting	
1		0		0		1		Receiving	

## NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

#### 45.6.2.9.4 Fields

Field	Function
31 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set  This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set.  After a read operation, the field's value clears to 0.  0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
30 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set  This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set.  After a read operation, the field's value clears to 0.  0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set  This bit indicates that a CRC error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received.  After a read operation, the field's value clears to 0.  0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set  This bit indicates that a form error has been detected by the receiver node in the data phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit.  After a read operation, the field's value clears to 0.  0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set  This bit indicates that a stuffing error has been detected in the data phase of CAN FD frames with the BRS bit set.  After a read operation, the field's value clears to 0.  0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-22 —	Reserved
21 ERROVR	Error Overrun  This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0b - Overrun has not occurred. 1b - Overrun has occurred.
20	Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set

*Table continues on the next page...*

## Memory map/register definition

Field	Function
ERRINT_FAST	<p>This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence. 1b - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.</p>
19 BOFFDONEINT	<p>Bus Off Done Interrupt</p> <p>This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence. 1b - FlexCAN module has completed Bus Off process.</p>
18 SYNCH	<p>CAN Synchronization Status</p> <p>This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description.</p> <p>0b - FlexCAN is not synchronized to the CAN bus. 1b - FlexCAN is synchronized to the CAN bus.</p>
17 TWRNINT	<p>Tx Warning Interrupt Flag</p> <p>If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.</p> <p>0b - No such occurrence. 1b - The Tx error counter transitioned from less than 96 to greater than or equal to 96.</p>
16 RWRNINT	<p>Rx Warning Interrupt Flag</p> <p>If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode.</p> <p>0b - No such occurrence. 1b - The Rx error counter transitioned from less than 96 to greater than or equal to 96.</p>
15 BIT1ERR	<p>Bit1 Error</p> <p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.</p> <p><b>NOTE:</b> This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.</p>
14 BIT0ERR	<p>Bit0 Error</p> <p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.</p>

Table continues on the next page...

Field	Function
	<p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.</p>
13 ACKERR	<p>Acknowledge Error</p> <p>This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - An ACK error occurred since last read of this register.</p>
12 CRCERR	<p>Cyclic Redundancy Check Error</p> <p>This bit indicates that a <b>Cyclic Redundancy Check</b> (CRC) error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - A CRC error occurred since last read of this register.</p>
11 FRMERR	<p>Form Error</p> <p>This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - A Form Error occurred since last read of this register.</p>
10 STFERR	<p>Stuffing Error</p> <p>This bit indicates that a <b>stuffing error</b> has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.</p>
9 TXWRN	<p>TX Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - TXERRCNT is greater than or equal to 96.</p>
8 RXWRN	<p>Rx Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.</p>
7 IDLE	<p>IDLE</p> <p>This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description.</p> <p>0b - No such occurrence. 1b - CAN bus is now IDLE.</p>

Table continues on the next page...

## Memory map/register definition

Field	Function
6 TX	<p>FlexCAN In Transmission</p> <p>This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description.</p> <p>0b - FlexCAN is not transmitting a message. 1b - FlexCAN is transmitting a message.</p>
5-4 FLTCONF	<p>Fault Confinement State</p> <p>This 2-bit field indicates the confinement state of the FlexCAN module.</p> <p>If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again.</p> <p>This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive.</p> <p>00b - Error Active 01b - Error Passive 1xb - Bus Off</p>
3 RX	<p>FlexCAN In Reception</p> <p>This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description.</p> <p>0b - FlexCAN is not receiving a message. 1b - FlexCAN is receiving a message.</p>
2 BOFFINT	<p>Bus Off Interrupt</p> <p>This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.</p>
1 ERRINT	<p>Error Interrupt</p> <p>This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence. 1b - Indicates setting of any error bit in the Error and Status register.</p>
0 WAKINT	<p>Wake-Up Interrupt</p> <p>This field applies when FlexCAN is in low-power mode under Self Wake Up mechanism:</p> <ul style="list-style-type: none"> <li>Doze mode</li> <li>Stop mode</li> </ul> <p>When a recessive-to-dominant transition is detected on the CAN bus and if MCR[WAKMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1.</p> <p>When MCR[SLFWAK] is negated, this flag is masked. The CPU must clear this flag before disabling the bit. Otherwise it will be set when SLFWAK is set again. Writing 0 has no effect.</p> <p>0b - No such occurrence. 1b - Indicates a recessive to dominant transition was received on the CAN bus.</p>

## 45.6.2.10 Interrupt Masks 2 Register (IMASK2)

### 45.6.2.10.1 Offset

Register	Offset
IMASK2	24h

### 45.6.2.10.2 Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

### 45.6.2.11.4 Fields

Field	Function
31-0 BUF31TO0M	<p>Buffer MBi Mask</p> <p>Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB31 to MB0.</p> <p><b>NOTE:</b> Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set.</p> <p>0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.</p>

## 45.6.2.12 Interrupt Flags 2 Register (IFLAG2)

### 45.6.2.12.1 Offset

Register	Offset
IFLAG2	2Ch

### 45.6.2.12.2 Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

### 45.6.2.12.3 Diagram

### 45.6.2.12.4 Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

## 45.6.2.13 Interrupt Flags 1 Register (IFLAG1)

### 45.6.2.13.1 Offset

Register	Offset
IFLAG1	30h

### 45.6.2.13.2 Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO , BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see [Rx FIFO](#). Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When MCR[RFEN] is negated, the FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGS asserted in the Rx FIFO region. When MCR[DMA] is negated, the FIFO must be empty. FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

#### 45.6.2.13.4 Fields

Field	Function
31-8 BUF31TO8I	<p>Buffer MBi Interrupt</p> <p>Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8.</p> <p>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.</p>
7 BUF7I	<p>Buffer MB7 Interrupt Or Rx FIFO Overflow</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>The BUF7I flag represents Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a mailbox.</p> <p>0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1</p>
6 BUF6I	<p>Buffer MB6 Interrupt Or Rx FIFO Warning</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p>

*Table continues on the next page...*

## Memory map/register definition

Field	Function
	<p>The BUF6I flag represents Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than four.</p> <p>0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1</p>
5 BUF5I	<p>Buffer MB5 Interrupt Or Frames available in Rx FIFO</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB5.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I.</p> <p>0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.</p>
4-1 BUF4TO1I	<p>Buffer MBi Interrupt Or Reserved</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.</p> <p><b>NOTE:</b> These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>The BUF4TO1I flags are reserved when MCR[RFEN] is set.</p> <p>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>
0 BUF0I	<p>Buffer MB0 Interrupt Or Clear FIFO bit</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGS. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions.</p> <p>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>

## 45.6.2.14 Control 2 Register (CTRL2)

### 45.6.2.14.1 Offset

Register	Offset
CTRL2	34h

### 45.6.2.14.2 Function

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

**Table 45-23. Rx FIFO filter: possible structures**

RFFN[3:0]	Number of Rx FIFO filter elements	Message buffers occupied by Rx FIFO and ID filter table	Remaining available mailboxes	Rx FIFO ID filter table elements affected by Rx individual masks	Rx FIFO ID filter table elements affected by Rx FIFO global mask

### 45.6.2.14.4 Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for errors detected in the data phase of fast CAN FD frames  This bit provides a mask for the ERRINT_FAST interrupt in ESR1 register. 0b - ERRINT_FAST error interrupt disabled. 1b - ERRINT_FAST error interrupt enabled.
30 BOFFDONEMSK	Bus Off Done Interrupt Mask  This bit provides a mask for the bus off done interrupt in ESR1 register. 0b - Bus off done interrupt disabled. 1b - Bus off done interrupt enabled.
29 —	Reserved
28 —	Reserved
27-24 RFFN	Number Of Rx FIFO Filters  This 4-bit field defines the number of Rx FIFO filters, as shown in <a href="#">Table 45-23</a> . The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Rx FIFO and ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB].  <b>NOTE:</b> Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available.  Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows:  $(SETUP_MB - 6) \times 4$

Table continues on the next page...

Field	Function
	<p>where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB].</p> <p>The number of remaining mailboxes available will be:</p> $(SETUP_MB - 8) - (RFFN \times 2)$ <p>If the number of Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• The number of the last remaining available mailboxes is defined by the smaller of NUMBER_OF_MB minus 1 and MCR[MAXMB].</li> <li>• If Rx Individual Mask registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.</li> </ul>
23-19 TASD	<p>Tx Arbitration Start Delay</p> <p>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See <a href="#">Tx arbitration start delay</a> for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p>
18 MRP	<p>Mailboxes Reception Priority</p> <p>If this bit is set the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - Matching starts from Rx FIFO and continues on mailboxes. 1b - Matching starts from mailboxes and continues on Rx FIFO.</p>
17 RRS	<p>Remote Request Storing</p> <p>If this bit is asserted a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame will be generated.</p> <p>If this bit is negated the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - Remote response frame is generated. 1b - Remote request frame is stored.</p>
16 EACEN	<p>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes</p> <p>This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0b - Rx mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1b - Enables the comparison of both Rx mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.</p>
15 TIMER_SRC	<p>Timer Source</p> <p>Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only.</p> <p>0b - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1b - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick.</p>
14 PREXCEN	<p>Protocol Exception Enable</p> <p>This bit enables the protocol exception feature.</p> <p>This field is writable only in Freeze mode.</p> <p><b>NOTE:</b> See Protocol exception event in the CAN Protocol standard (ISO 11898-1) for details.</p>

*Table continues on the next page...*

## Memory map/register definition

Field	Function
	0b - Protocol exception is disabled. 1b - Protocol exception is enabled.
13 —	Reserved
12 ISOCANFDEN	<p>ISO CAN FD Enable</p> <p>This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see <a href="#">CAN FD ISO compliance</a>).</p> <p>This field is writable only in Freeze mode.</p> <p><b>NOTE:</b> FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1).            0b - FlexCAN operates using the non-ISO CAN FD protocol.            1b - FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).</p>
11 EDFLTDIS	<p>Edge Filter Disable</p> <p>This bit disables the edge filter used during the bus integration state.</p> <p>When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition.</p> <p>This field is writable only in Freeze mode.</p> <p><b>NOTE:</b> See Bus Integration state in the CAN Protocol standard (ISO 11898-1) for details.            0b - Edge filter is enabled            1b - Edge filter is disabled</p>

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	VPS	IMB						0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### 45.6.2.15.4 Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see <a href="#">Highest-priority mailbox first</a> ). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.
15 —	Reserved
14 VPS	Valid Priority Status This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox.  <b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0b - Contents of IMB and LPTM are invalid. 1b - Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases: <ul style="list-style-type: none"><li>• During arbitration, if an ESR2[LPTM] is found and it is inactive.</li><li>• If ESR2[IMB] is not asserted and a frame is transmitted successfully.</li></ul> This bit is always cleared in start of arbitration (see <a href="#">Arbitration process</a> ).

Table continues on the next page...

Field	Function
	<b>NOTE:</b> ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0b - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox. 1b - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.
12-0	Reserved
—	

## 45.6.2.16 CRC Register (CRCR)

### 45.6.2.16.1 Offset

Register	Offset
CRCR	44h

### 45.6.2.16.2 Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

#### NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

### 45.6.2.16.3 Diagram

#### 45.6.2.16.4 Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Mailbox This field indicates the number of the mailbox corresponding to the value in CRCR[TXCRC] field.
15 —	Reserved
14-0 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register.

#### 45.6.2.17 Rx FIFO Global Mask Register (RXFGMASK)

##### 45.6.2.17.1 Offset

Register	Offset
RXFGMASK	48h

##### 45.6.2.17.2 Function

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

**Table 45-24. Correspondence of Rx FIFO global mask bits to IDF fields**

Rx FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB <sup>1</sup>	RXIDC <sup>2</sup>	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]	—	—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.

### 45.6.2.17.3 Diagram

### 45.6.2.17.4 Fields

Field	Function
31-0 FGM	Rx FIFO Global Mask Bits  These bits mask the ID filter table elements bits in a perfect alignment.  0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

### 45.6.2.18 Rx FIFO Information Register (RXFIR)

### 45.6.2.18.1 Offset

Register	Offset
RXFIR	4Ch

### 45.6.2.18.2 Function

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO. Also, its output is updated whenever the output of the Rx FIFO is updated with the next message. See [Rx FIFO](#) for instructions on reading this register.

### 45.6.2.18.3 Diagram

### 45.6.2.18.4 Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is asserted.

## 45.6.2.19 CAN Bit Timing Register (CBT)

### 45.6.2.19.1 Offset

Register	Offset
CBT	50h

### 45.6.2.19.2 Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

#### NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

#### NOTE

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

#### NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

### 45.6.2.19.3 Diagram

## 45.6.2.19.4 Fields

Field	Function
31 BTF	Bit Timing Format Enable  Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only. 0b - Extended bit time definitions disabled. 1b - Extended bit time definitions enabled.
30-21 EPRESDIV	Extended Prescaler Division Factor  This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range.  The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see <a href="#">Protocol timing</a> ). This field can be written only in Freeze mode because it is blocked by hardware in other modes.  $\text{Sclock frequency} = \text{PE clock frequency} / (\text{EPRESDIV} + 1)$
20-16 ERJW	Extended Resync Jump Width  This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range.  One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  $\text{Resync Jump Width} = \text{ERJW} + 1.$
15-10 EPROPSEG	Extended Propagation Segment  This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  $\text{Propagation Segment Time} = (\text{EPROPSEG} + 1) \times \text{Time-Quanta.}$ $\text{Time-Quantum} = \text{one Sclock period.}$
9-5 EPSEG1	Extended Phase Segment 1  This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  $\text{Phase Buffer Segment 1} = (\text{EPSEG1} + 1) \times \text{Time-Quanta.}$ $\text{Time-Quantum} = \text{one Sclock period.}$
4-0 EPSEG2	Extended Phase Segment 2  This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  $\text{Phase Buffer Segment 1} = (\text{EPSEG2} + 1) \times \text{Time-Quanta.}$ $\text{Time-Quantum} = \text{one Sclock period.}$

## 45.6.2.20 Rx Individual Mask Registers (RXIMR0 - RXIMR63)

### 45.6.2.20.1 Offset

For n = 0 to 63:

Register	Offset
RXIMRn	880h + (n × 4h)

### 45.6.2.20.2 Function

The RX Individual Mask registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

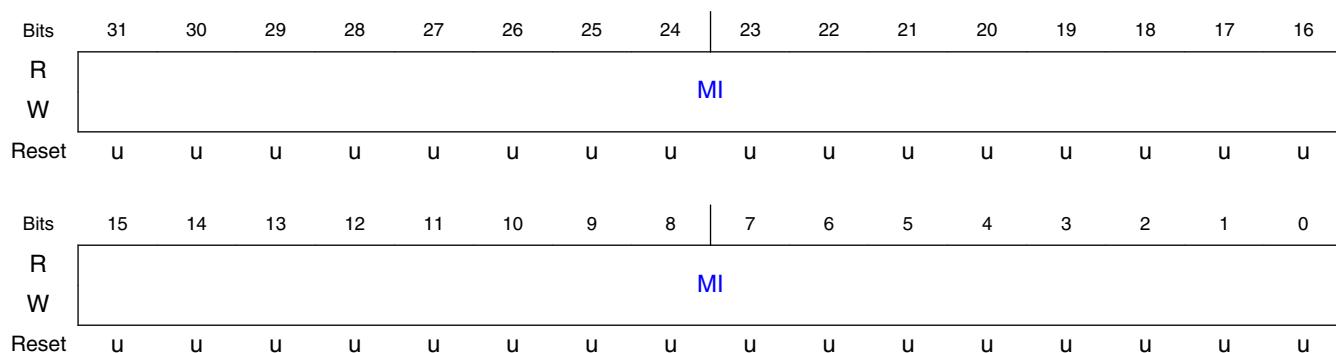

When the Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see [Rx FIFO](#)).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See [Bus interface](#) for more information.

### 45.6.2.20.3 Diagram

### 45.6.2.20.4 Fields

Field	Function
31-0 MI	<p>Individual Mask Bits</p> <p>Each individual mask bit masks the corresponding bit in both the mailbox filter and Rx FIFO ID filter table element in distinct ways.</p> <p>For mailbox filters, see the RXMGMASK register description.</p> <p>For Rx FIFO ID filter table elements, see the RXFGMASK register description.</p> <p>0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.</p>

### 45.6.2.21 CAN FD Control Register (FDCTRL)

#### 45.6.2.21.1 Offset

Register	Offset
FDCTRL	C00h

#### 45.6.2.21.2 Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

**Table 45-25. Number of message buffers**

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

**NOTE**

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

**45.6.2.21.4 Fields**

Field	Function
31 FDRATE	Bit Rate Switch Enable  This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages.  The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle, or Bus Off state, or when the current frame under reception or transmission reaches the interframe space.  By negating FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, no matter what the value is in the BRS bit of the Tx MBs.  0b - Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1b - Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
30-27 —	Reserved
26-25 —	Reserved

Table continues on the next page...

Field	Function
24 —	Reserved
23-22 —	Reserved
21 —	Reserved
20-19 MBDSR1	<p>Message Buffer Data Size for Region 1</p> <p>This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R1 of message buffers allocated in RAM.</p> <p>It can be written in Freeze mode only.</p> <ul style="list-style-type: none"> <li>00b - Selects 8 bytes per message buffer.</li> <li>01b - Selects 16 bytes per message buffer.</li> <li>10b - Selects 32 bytes per message buffer.</li> <li>11b - Selects 64 bytes per message buffer.</li> </ul>
18 —	Reserved
17-16 MBDSR0	<p>Message Buffer Data Size for Region 0</p> <p>This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R0 of message buffers allocated in RAM.</p> <p>It can be written in Freeze mode only.</p> <ul style="list-style-type: none"> <li>00b - Selects 8 bytes per message buffer.</li> <li>01b - Selects 16 bytes per message buffer.</li> <li>10b - Selects 32 bytes per message buffer.</li> <li>11b - Selects 64 bytes per message buffer.</li> </ul>
15 TDCEN	<p>Transceiver Delay Compensation Enable</p> <p>This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only.</p> <p><b>NOTE:</b> See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details.</p> <p><b>NOTE:</b> TDC must be disabled when Loop Back mode is enabled (see CTRL1[LPB]).</p> <ul style="list-style-type: none"> <li>0b - TDC is disabled</li> <li>1b - TDC is enabled</li> </ul>
14 TDCFAIL	<p>Transceiver Delay Compensation Fail</p> <p>This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see <a href="#">Transceiver delay compensation</a>). TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write one to clear it.</p> <ul style="list-style-type: none"> <li>0b - Measured loop delay is in range.</li> <li>1b - Measured loop delay is out of range.</li> </ul>
13 —	Reserved
12-8 TDCOFF	<p>Transceiver Delay Compensation Offset</p> <p>This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See <a href="#">Transceiver delay compensation</a> for more details on how the loop delay measurement is performed.</p>

*Table continues on the next page...*

## Memory map/register definition

Field	Function
	TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see <a href="#">Protocol timing</a> for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation.  <b>NOTE:</b> It is not recommended to have TDCOFF equal to zero.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value  This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK).  See <a href="#">Protocol timing</a> for more details on how the loop delay measurement is performed.

## 45.6.2.22 CAN FD Bit Timing Register (FDCBT)

### 45.6.2.22.1 Offset

Register	Offset
FDCBT	C04h

### 45.6.2.22.2 Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

#### NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

#### NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

Table continues on the next page...

## Memory map/register definition

Field	Function
	Time-Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1  This 3-bit field defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta.  Time-Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2  This 3-bit field defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta.  Time-Quantum = one Sclock period.

## 45.6.2.23 CAN FD CRC Register (FDCRC)

### 45.6.2.23.1 Offset

Register	Offset
FDCRC	C08h

### 45.6.2.23.2 Function

This register provides information about the CRC of transmitted messages.

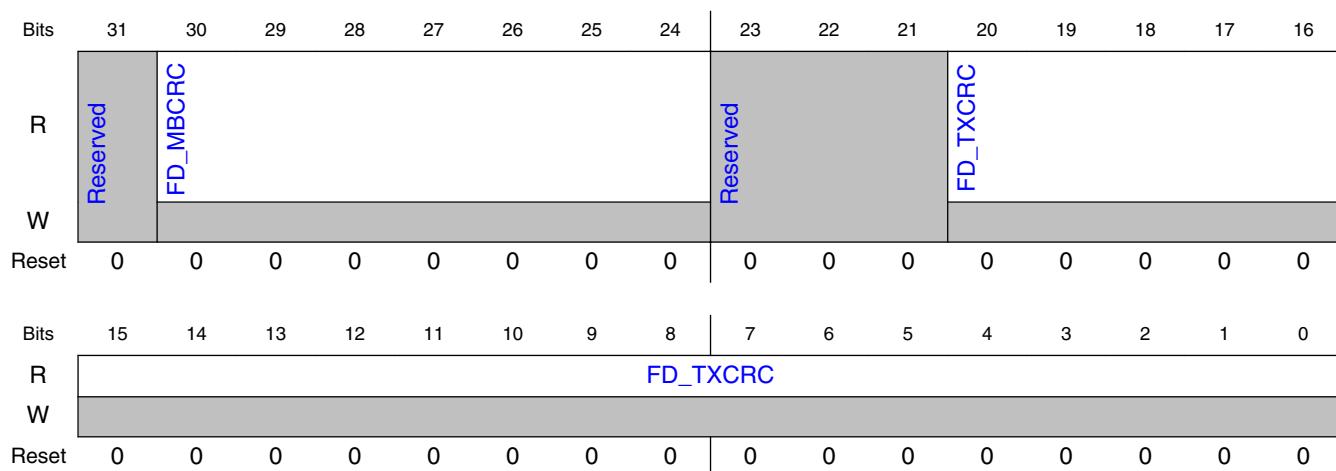

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC\_15 polynomial is used for all frames in CAN format. The CRC\_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC\_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

$\text{CRC}_{15} = \text{C}599\text{h}: (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$   
 $\text{CRC}_{17} = \text{3}685\text{Bh}: (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$   
 $\text{CRC}_{21} = \text{3}02899\text{h}: (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$

**Figure 45-28. CRC polynomial used on CAN frame****NOTE**

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

**45.6.2.23.3 Diagram****45.6.2.23.4 Fields**

Field	Function
31	Reserved
—	
30-24 FD_MBCRC	CRC Mailbox Number for FD_TXCRC  This field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames.  It reports the same information as in CRCR[MBCRC].
23-21	Reserved
—	
20-0 FD_TXCRC	Extended Transmitted CRC value  This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes.

## Memory map/register definition

Field	Function
	For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC register.

### 45.6.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–47Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See [FlexCAN memory partition for CAN FD](#) for more detailed information.

**Table 45-26. Message buffer structure — example with 64-byte payload**

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0
0h	EDL	BRS	ESI		CODE		SRR	IDE	RTR		DLC					TIME STAMP

			= Unimplemented or reserved															

**EDL** — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

### BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

### ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

### CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 45-27](#) and [Table 45-28](#). See [Functional description](#) for additional information.

**Table 45-27. Message buffer code for Rx buffers**

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
0000b: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0100b: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the <a href="#">Move-in</a> process), the CODE field is automatically updated to FULL.
0010b: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See <a href="#">Matching process</a> for matching details related to FULL code.

*Table continues on the next page...*

**Table 45-27. Message buffer code for Rx buffers (continued)**

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.
0110b: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.
1010b: <b>RANSWER<sup>4</sup></b> — A frame was configured to recognize a Remote Request frame and transmit a Response frame in return. <sup>5</sup>	RANSWER	—	TANSWER(1110b)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110b). See <a href="#">Matching process</a> for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
					request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY <sup>6</sup>	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 45-28. Message buffer code for Tx buffers**

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1000b: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.
1001b: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
1100b: DATA — MB is a Tx data frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.

Table continues on the next page...

**Table 45-28. Message buffer code for Tx buffers (continued)**

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details.

**SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 45-27](#), [Table 45-28](#), and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

**1** = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

**0** = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### NOTE

When configuring CAN FD frames, the RTR bit must be negated.

### DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see [Table 45-26](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 45-29](#)).

### TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### PRI0 — Local priority

This 3-bit field is used only when MCR[LPRI0\_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE ( $n$ ) is valid only if  $n$  is less than DLC as shown in the table below.

**Table 45-29. DATA BYTEs validity**

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

#### 45.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

**Table 45-30. RAM partition**

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload

**Table 45-30. RAM partition**

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
			MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Then the following table indicates how the message buffers will be arranged in RAM.

**Table 45-31. RAM partition example**

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31
1	FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52

## 45.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

**Table 45-32. 8-byte message buffers**

## 45.6.6 Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 80h–8Ch contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 45-36. Rx FIFO structure**

31	28	24	23	22	21	20	19	18	17	16	15	8	7	0												
80h	IDHIT			SRR	IDE	RTR	DLC				TIME STAMP															
84h		ID standard								ID extended																
88h	Data byte 0		Data byte 1					Data byte 2			Data byte 3															
8Ch	Data byte 4		Data byte 5					Data byte 6			Data byte 7															
90h–DCh	Reserved																									
E0h	ID filter table element 0																									
E4h	ID filter table element 1																									
E8h–2D4h	ID filter table elements 2 to 125																									
2D8h	ID filter table element 126																									
2DCh	ID filter table element 127																									
		= Unimplemented or reserved																								

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

**Table 45-37. ID table structure**

Format 31 30 29 24 23 16 15 14 13 8 7 1 0												
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)									
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)			RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)				
C	RXIDC_0 (std/ext = 31–24)			RXIDC_1 (std/ext = 23–16)	RXIDC_2 (std/ext = 15–8)			RXIDC_3 (std/ext = 7–0)				
	= Unimplemented or Reserved											

**RTR** — Remote frame

This bit specifies if remote frames are accepted into the FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

**IDE** — Extended frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

**RXIDA** — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

**RXIDB\_0, RXIDB\_1** — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

**RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

**IDHIT** — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. See [Rx FIFO](#) for more information.

# Chapter 46

## Keypad Port (KPP)

### 46.1 Chip-specific KPP information

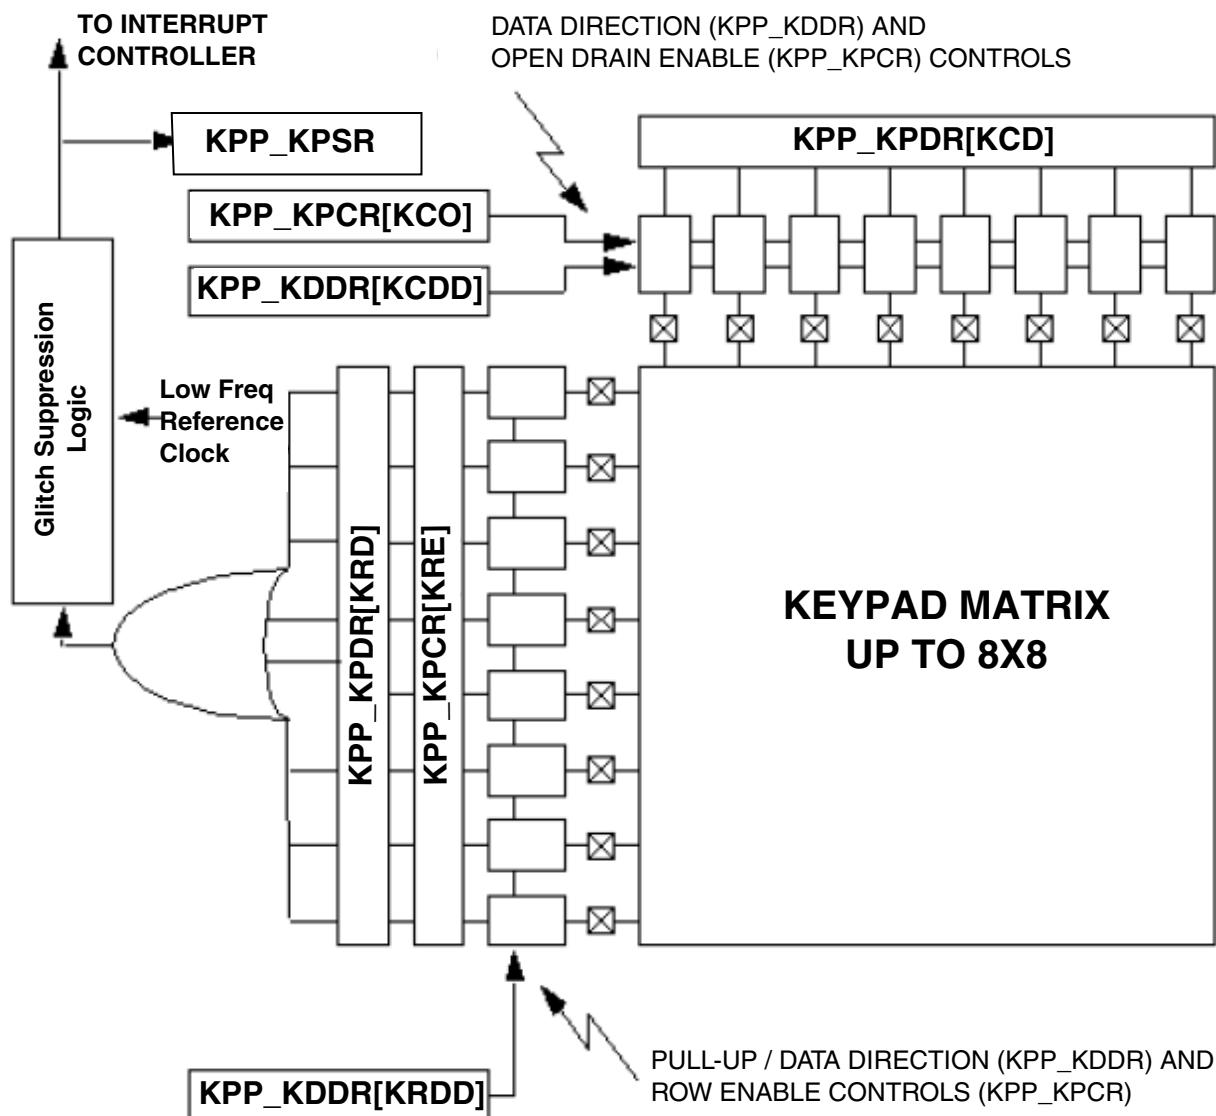

Table 46-1. Reference links to related information

### 46.2 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

## 46.2.1 Block diagram

**Figure 46-1. KPP Peripheral Block Diagram**

## 46.2.2 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection

- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

## 46.3 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock (ipg\_clk\_32k) is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

### 46.3.1 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

### 46.3.2 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

### 46.3.3 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

### 46.3.4 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next software layer.

The KPP may be used to control the debounce period, but it must be defined in software by the user's application. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

### 46.3.5 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP can interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

### 46.3.6 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock (ipg\_clk\_32k) source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

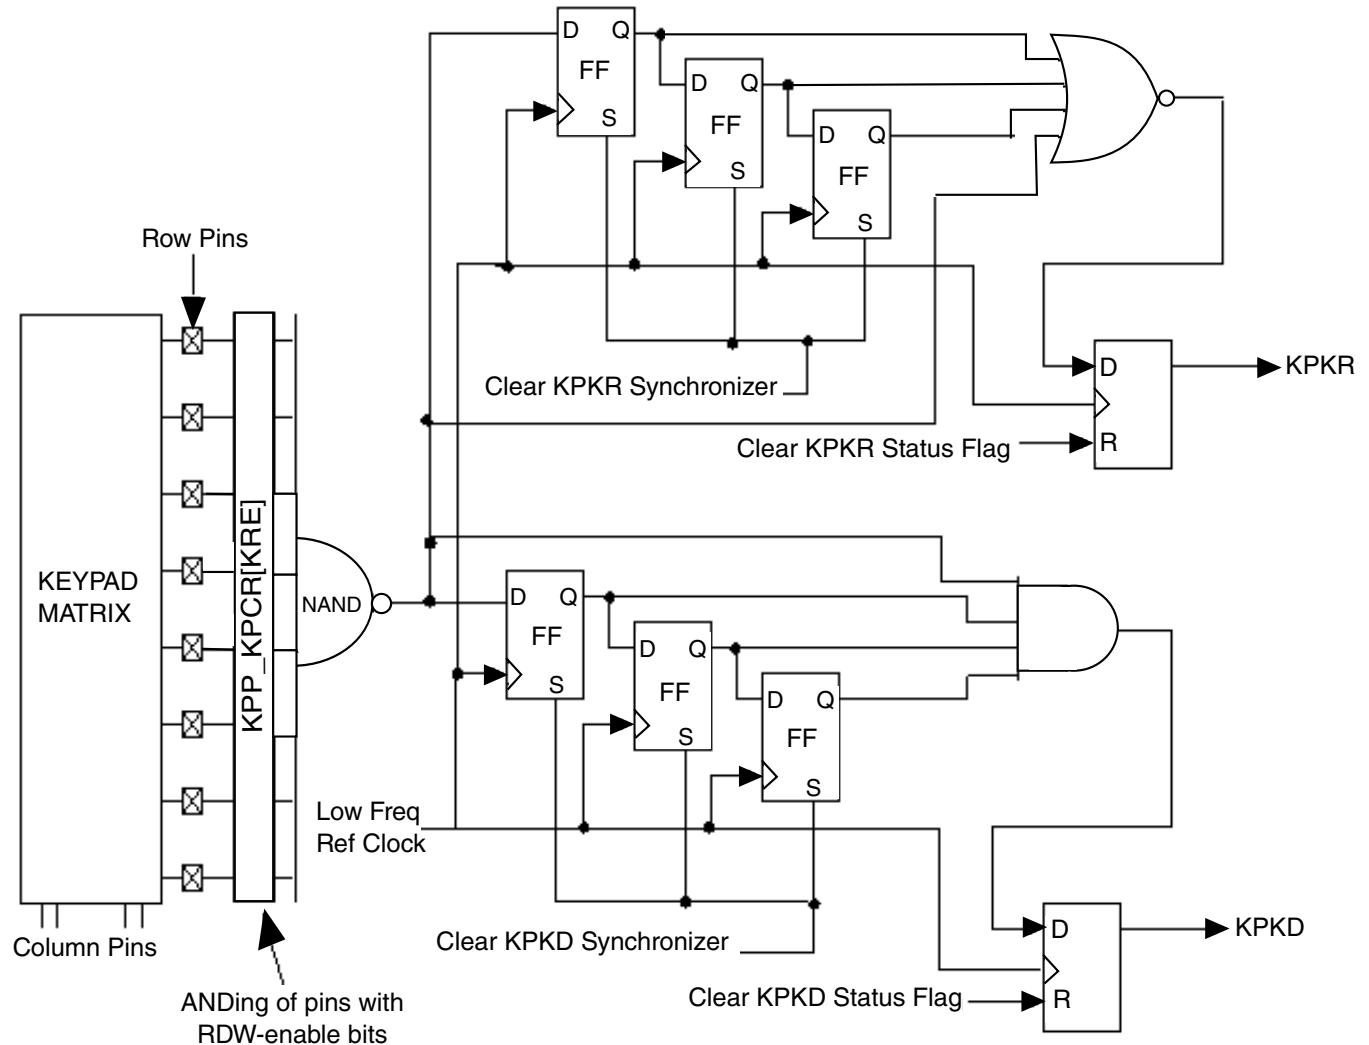

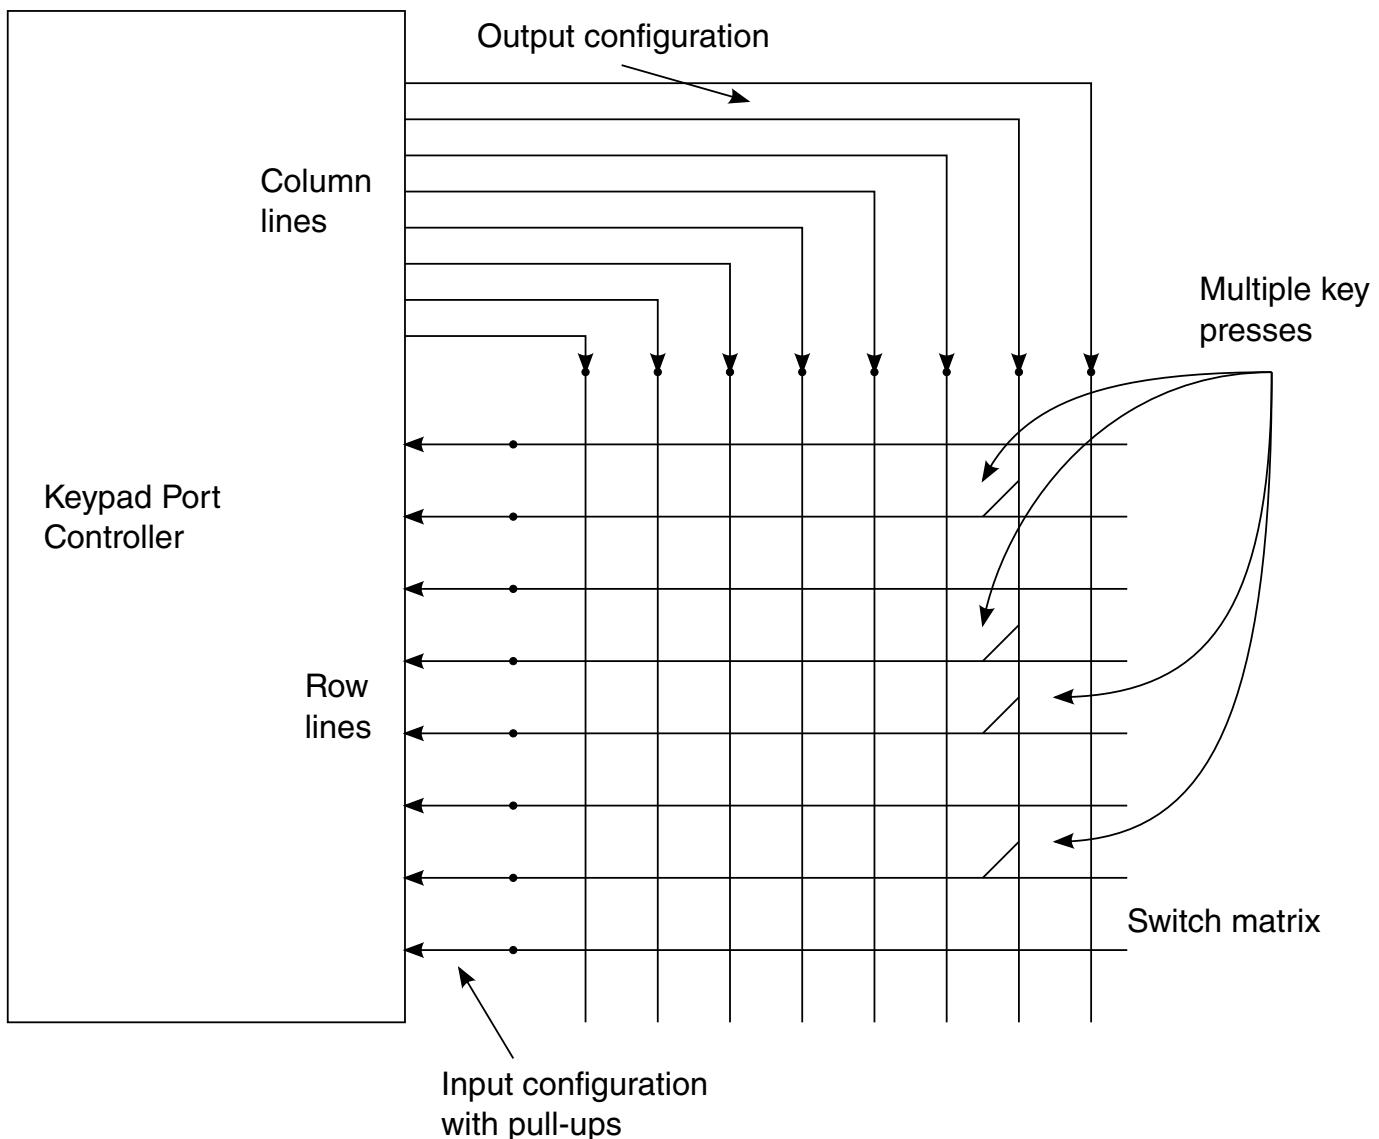

Figure 46-2. Keypad Synchronizer Functional Diagram

### 46.3.7 Multiple Key Closures

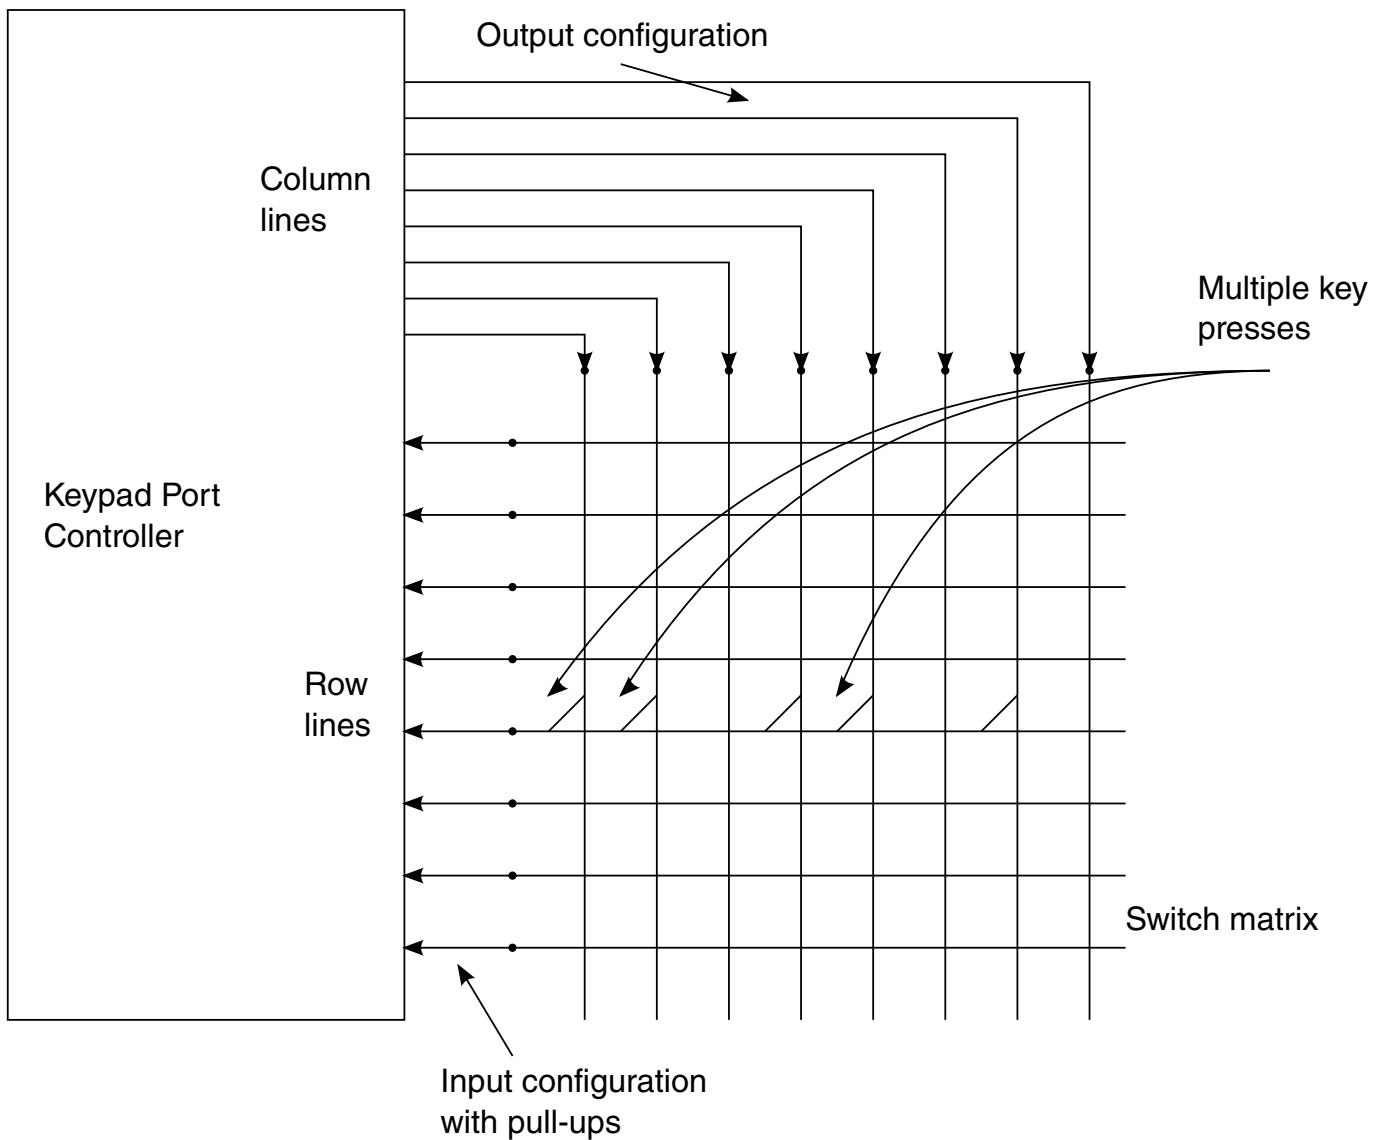

Using the key press and key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly (See [Initialization/Application Information](#) for more information).

The following figures illustrate the interface of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected.

Similarly, when keys present on same column line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

**Figure 46-3. Multiple Key Presses on Same Column Line (Simplified View)**

**Figure 46-4. Multiple Key Presses on Same Row Line (Simplified View)**

#### NOTE

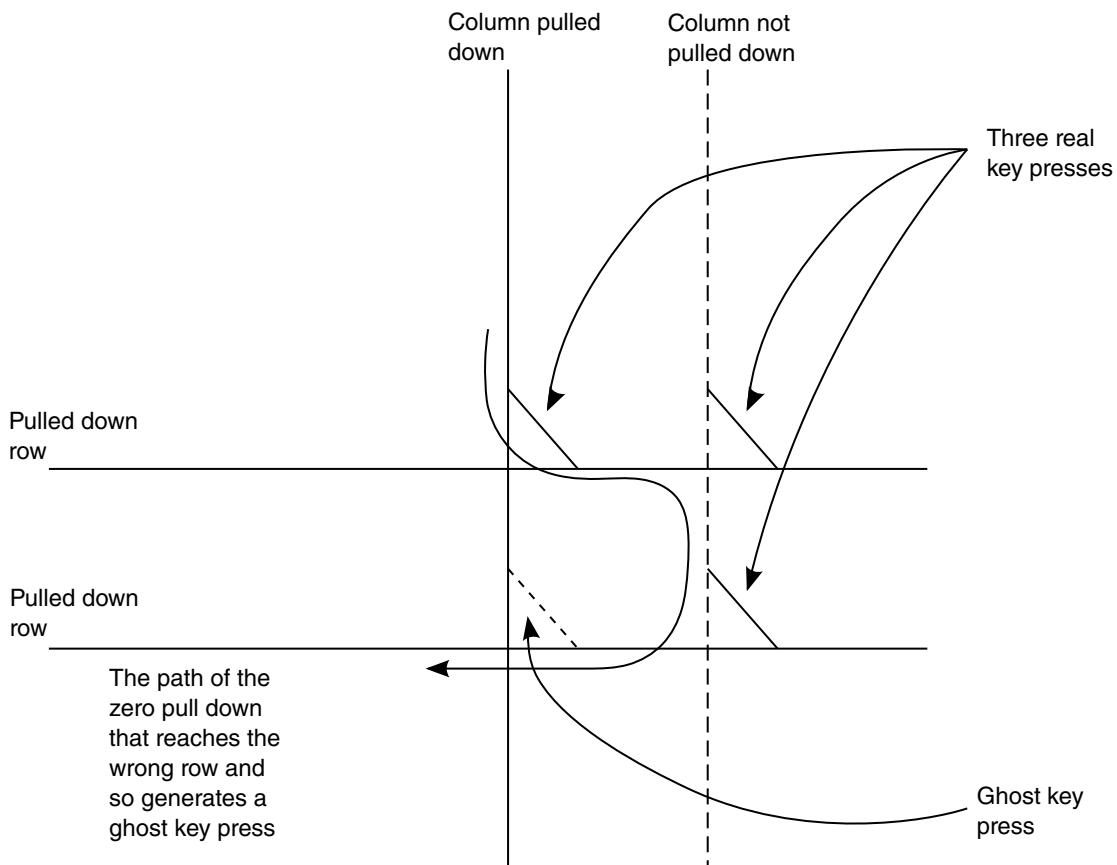

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

#### 46.3.7.1 Ghost Key Problem and Correction

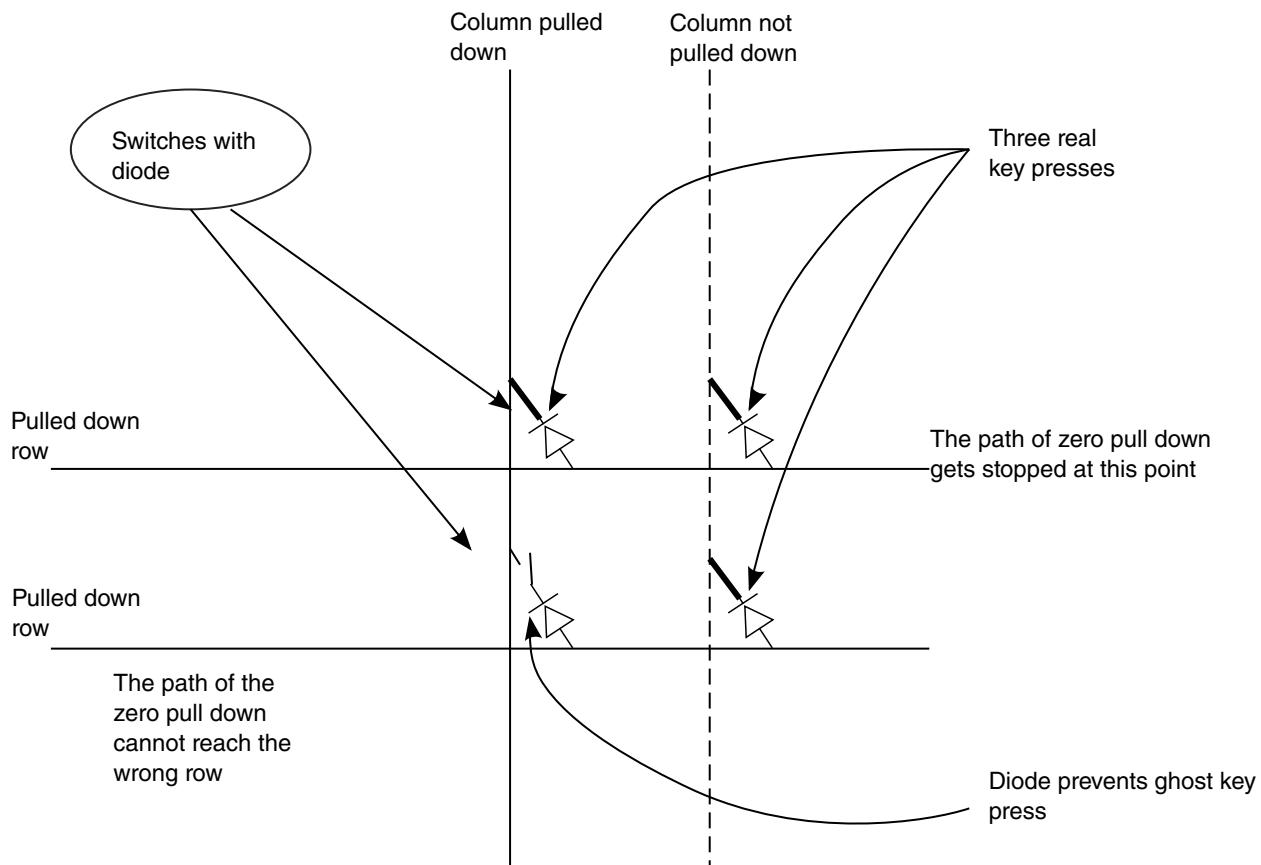

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As seen in [Figure 46-5](#), three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see [Figure 46-6](#)).

**Figure 46-5. Decoding Wrong Three- Key-Presses**

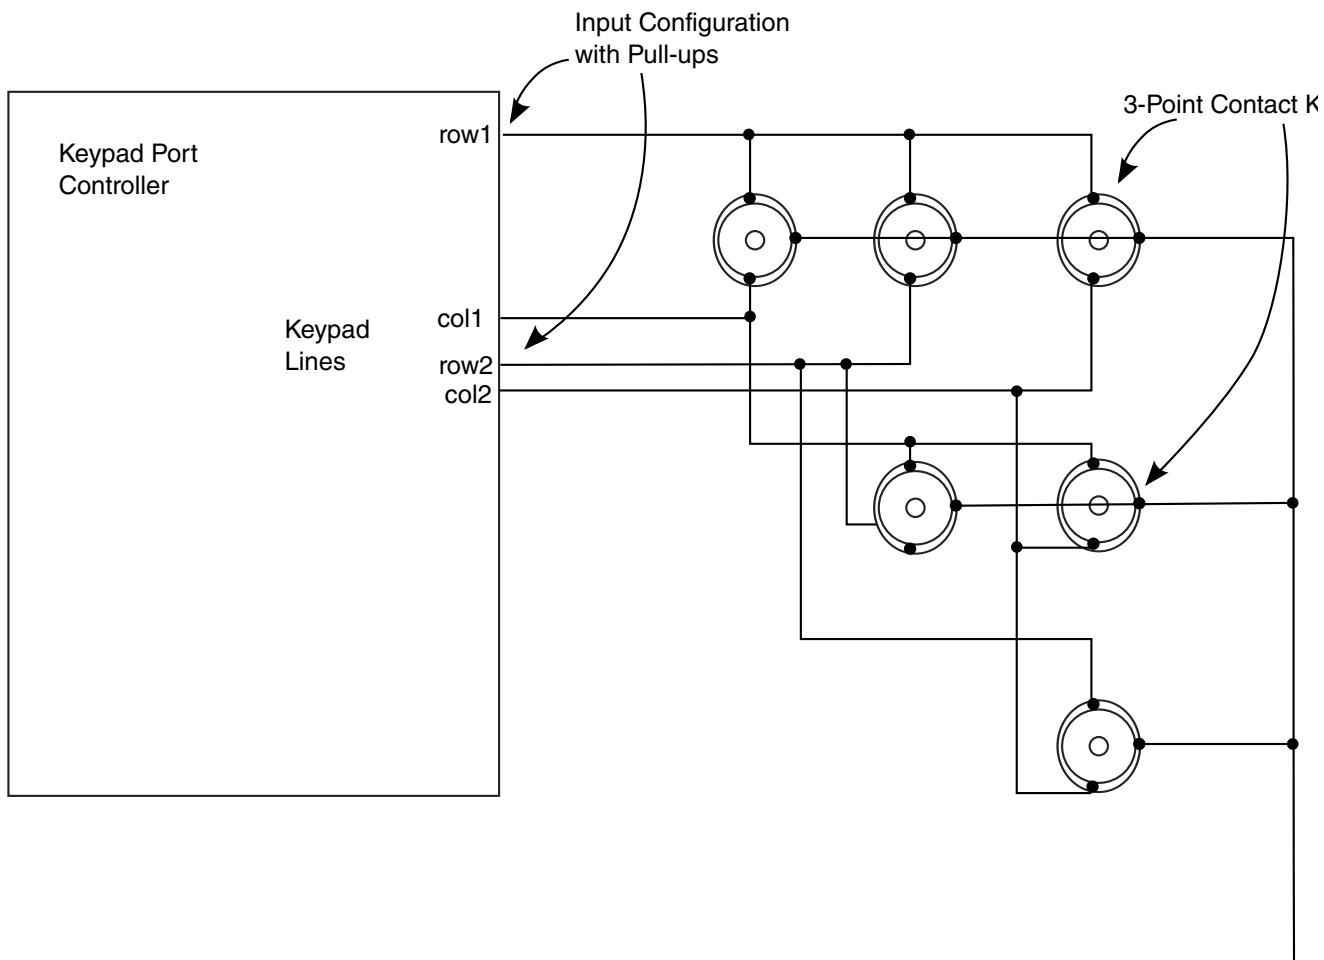

**Figure 46-6. Matrix with "Ghost" Key Protections**

### 46.3.8 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in [Figure 46-7](#), two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

**Figure 46-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)**

### 46.3.9 Clocks

The table found here describes the clock sources for KPP. Please see clock control block for clock setting, configuration and gating information.

**Table 46-2. KPP Clocks**

Clock name	Description
ipg_clk_32k	Low-frequency reference clock (32 kHz)
ipg_clk_s	Peripheral access clock

## 46.4 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide. Please see IOMUX Controller for KPP pin mux assignments.

See the table below for the list of external signals.

**Table 46-3. KPP External Signals**

Name	Direction	Function	Reset State	Pull-Up
KEY_COL[7:0]	IO	Column input or output pin, from chip	0	Active <sup>1</sup>
KEY_ROW[7:0]	IO	Row input or output pin, from chip	1	Active <sup>1</sup>

1. The corresponding pads are required to be pull-up enabled.

### 46.4.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP\_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP\_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

### 46.4.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP\_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP\_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

**Table 46-4. Keypad Port Column Modes**

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

**NOTE**

Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced. Totem pole mode is to be used temporarily on the column pins to discharge the lines only, but should be switched to open-drain mode for normal operation.

#### **46.4.3 Generation of Transfer Error Signal on Peripheral Bus**

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

### **46.5 Initialization/Application Information**

#### **46.5.1 Typical Keypad Configuration and Scanning Sequence**

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP\_KPCR[KRE]).
2. Write 0s to KPP\_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP\_KPCR[KCO]).
4. Configure columns as output (KPP\_KDDR[KCDD]) and rows as input (KPP\_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

#### **46.5.2 Key Press Interrupt Scanning Sequence**

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP\_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).

4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP\_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

### **46.5.3 Additional Comments**

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

## **46.6 Memory Map and Register Definition**

### **46.6.1 KPP register descriptions**

The KPP contains four registers.

#### **46.6.1.1 KPP memory map**

KPP base address: 401F\_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Keypad Control Register (KPCR)	16	RW	0000h
2h	Keypad Status Register (KPSR)	16	RW	0400h
4h	Keypad Data Direction Register (KDDR)	16	RW	0000h
6h	Keypad Data Register (KPDR)	16	RW	0000h

## 46.6.1.2 Keypad Control Register (KPCR)

### 46.6.1.2.1 Offset

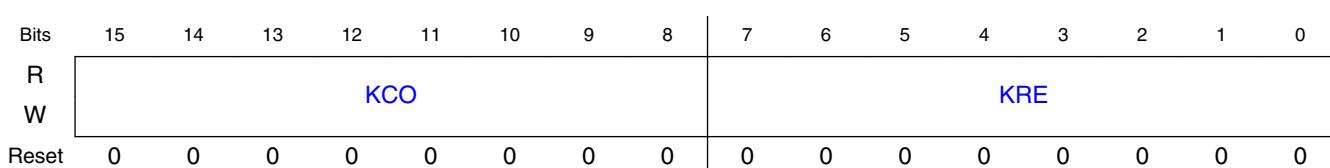

Register	Offset
KPCR	0h

### 46.6.1.2.2 Function

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP\_KPCR register is byte- or half-word-addressable.

### 46.6.1.2.3 Diagram

### 46.6.1.2.4 Fields

Field	Function
15-8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input.

*Table continues on the next page...*

## Memory Map and Register Definition

Field	Function
	<p><b>NOTE:</b> Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin.</p> <p>00000000b - Column strobe output is totem pole drive. 00000001b - Column strobe output is open drain.</p>
7-0 KRE	<p>KRE</p> <p>Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set.</p> <p>00000000b - Row is not included in the keypad key press detect. 00000001b - Row is included in the keypad key press detect.</p>

### 46.6.1.3 Keypad Status Register (KPSR)

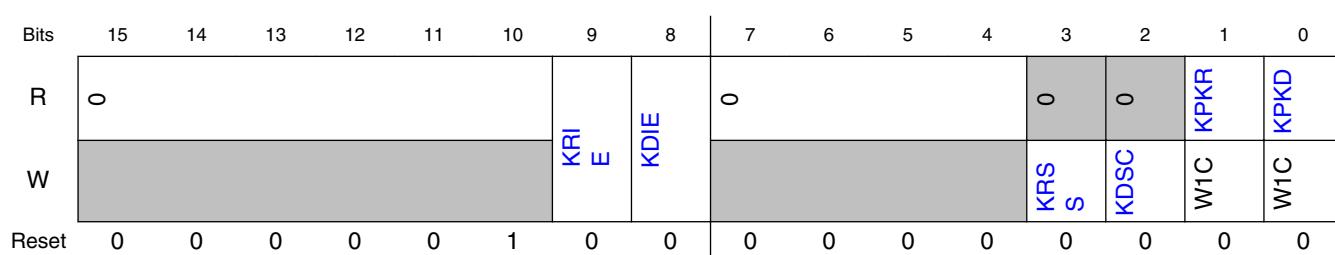

#### 46.6.1.3.1 Offset

Register	Offset
KPSR	2h

#### 46.6.1.3.2 Function

The Keypad Status Register reflects the state of the key press detect circuit. The KPP\_KPSR register is byte- or half-word-addressable.

#### 46.6.1.3.3 Diagram

#### 46.6.1.3.4 Fields

Field	Function
15-10 —	- Reserved
9 KRIE	KRIE  Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain.  0b - No interrupt request is generated when KPKR is set. 1b - An interrupt request is generated when KPKR is set.
8 KDIE	KDIE  Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain.  0b - No interrupt request is generated when KPKD is set. 1b - An interrupt request is generated when KPKD is set.
7-4 —	- Reserved, should be cleared
3 KRSS	KRSS  Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit.  Reads return a value of "0".  0b - No effect 1b - Set bits which sets keypad release synchronizer chain
2 KDSC	KDSC  Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit.  Reads return a value of "0".  0b - No effect 1b - Set bits that clear the keypad depress synchronizer chain
1 KPKR	KPKR  Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents.  Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1".  0b - No key release detected 1b - All keys have been released

Table continues on the next page...

Field	Function
0 KPKD	<p>Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock (ipg_clk_32k) elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys.</p> <p>Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents.</p> <p>0b - No key presses detected 1b - A key has been depressed</p>

## 46.6.1.4 Keypad Data Direction Register (KDDR)

### 46.6.1.4.1 Offset

Register	Offset
KDDR	4h

### 46.6.1.4.2 Function

The bits in the KPP\_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP\_KDDR register is byte- or half-word addressable.

#### NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

### 46.6.1.4.3 Diagram

Field	Function
15-8 KCDD	KCDD Keypad Column Data Direction Register. Setting a bit configures the corresponding COL $n$ pin as an output (where $n = 7$ through 0). 00000000b - COL $n$ pin is configured as an input. 00000001b - COL $n$ pin is configured as an output.
7-0 KRDD	KRDD Keypad Row Data Direction. Setting a bit configures the corresponding ROW $n$ pin as an output (where $n = 7$ through 0). 00000000b - ROW $n$ pin configured as an input. 00000001b - ROW $n$ pin configured as an output.

### 46.6.1.5 Keypad Data Register (KPDR)

#### 46.6.1.5.1 Offset

Register	Offset
KPDR	6h

#### 46.6.1.5.2 Function

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP\_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

### 46.6.1.5.3 Diagram

## Low Power Inter-Integrated Circuit (LPI2C)

### 47.1 Chip-specific LPI2C information

Table 47-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

#### NOTE

For LPI2C on this device, only LPI2C1 fully supports the 5 wires, while other instances (LPI2C2, ...) have only 2 wires.

### 47.2 Overview

The LPI2C is a low power Inter-Integrated Circuit (I<sup>2</sup>C) module that supports an efficient interface to an I<sup>2</sup>C bus as a master and/or as a slave.

- Implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- Uses little CPU overhead, with DMA offloading of FIFO register accesses.
- Continues operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

### NOTE

The I<sup>2</sup>C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

#### 47.2.1 Block diagram

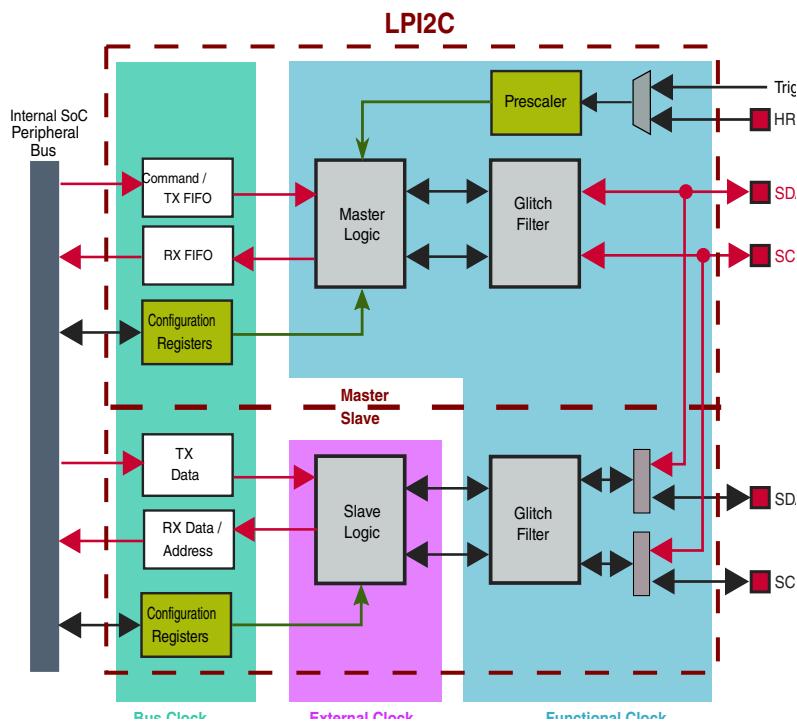

Figure 47-1. LPI2C block diagram

#### 47.2.2 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- High speed mode (HS) in master mode, if SCL pin implements current source pull-up (device-specific)

- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism.
  - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4 words (8-bit transmit data + 3-bit command).
- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

## 47.3 Functional description

### 47.3.1 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

#### 47.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP condition; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master automatically transmits a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example, HS-mode master code) must be followed by a STOP or (repeated) START condition.

### 47.3.1.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle ([MSR\[BBF\]](#)). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by [MCFGR2\[BUSIDLE\]](#)). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master initiates a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to ([MCCR0\[CLKLO\]](#) + 1) multiplied by the prescaler ([MCFGR1\[PRESCALE\]](#)).
- Transmit a START condition and address byte using the timing configuration in [Master Clock Configuration 0 \(MCCR0\)](#); if a high speed mode transfer is configured, then the timing configuration from [Master Clock Configuration 1 \(MCCR1\)](#) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or [MCFGR1\[AUTOSTOP\]](#). A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to [MCR\[MEN\]](#) being clear or automatically due to mode entry), the LPI2C continues to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C generates a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this results in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and [MCFGR1\[AUTOSTOP\]](#) is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

### 47.3.1.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and delay the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the [MCFGR0\[RDMO\]](#) control bit. When clearing the [MCFGR0\[RDMO\]](#) control bit following a data match, clear [MCFGR0\[RDMO\]](#) before clearing [MSR\[DMF\]](#), to allow all subsequent data to be received.

### 47.3.1.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode ([Master Clock Configuration 1 \(MCCR1\)](#)) and other modes ([Master Clock Configuration 0 \(MCCR0\)](#)). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

**Table 47-2. Timing Parameters**

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	$(\text{CLKHI} + \text{CLKLO} + 2 + \text{SCL\_LATENCY}) \times (2^{\wedge} \text{PRESCALE})$
hold time (repeated) START condition	tHD:STA	$(\text{SETHOLD} + 1) \times (2^{\wedge} \text{PRESCALE})$
LOW period of the SCL clock	tLOW	$(\text{CLKLO} + 1) \times (2^{\wedge} \text{PRESCALE})$
HIGH period of the SCL clock	tHIGH	$(\text{CLKHI} + 1 + \text{SCL\_LATENCY}) \times (2^{\wedge} \text{PRESCALE})$
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	$(\text{SETHOLD} + 1 + \text{SCL\_LATENCY}) \times (2^{\wedge} \text{PRESCALE})$
data hold time	tHD:DAT	$(\text{DATAVD} + 1) \times (2^{\wedge} \text{PRESCALE})$
data setup time	tSU:DAT	$(\text{SDA\_LATENCY} + 1) \times (2^{\wedge} \text{PRESCALE})$

*Table continues on the next page...*

**Table 47-2. Timing Parameters (continued)**

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-up resistor sizing. A larger rise time increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

**Table 47-3. Synchronization Latency**

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ( (2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE) )
SDA_LATENCY	ROUNDDOWN ( (2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE) )

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

**Table 47-4. LPI2C Timing Parameter Restrictions**

Timing Parameter	Minimum	Maximum	Comment
CLKLO	0x03	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	0x01	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	0x02	-	Also: SETHOLD x (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	0x01	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	0x00	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification; this depends on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

**Table 47-5. LPI2C Example Timing Configurations**

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSLC / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbps	0x0	0x0/0x0	0x04	0x0B	0x05	0x02
Fast+	8 MHz	1 Mbps	0x0	0x0/0x0	0x02	0x03	0x01	0x01
Fast	48 MHz	400 kbps	0x0	0x1/0x1	0x1D	0x3E	0x35	0x0F
Fast	48 MHz	400 kbps	0x2	0x1/0x1	0x07	0x11	0x0B	0x03
Fast+	48 MHz	1 Mbps	0x2	0x1/0x1	0x03	0x06	0x04	0x04
HS-mode	48 MHz	3.2 Mbps	0x0	0x0/0x0	0x07	0x08	0x03	0x01
Fast	60 MHz	400 kbps	0x1	0x2/0x2	0x11	0x28	0x1F	0x08
Fast+	60 MHz	1 Mbps	0x1	0x2/0x2	0x07	0x0F	0x0B	0x01
HS-mode	60 MHz	3.33 Mbps	0x1	0x0/0x0	0x04	0x04	0x02	0x01

### 47.3.1.5 Error Conditions

The LPI2C master monitors for errors while it is active, the following conditions generates an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets [MSR\[ALF\]](#)).
- Transmitting data on SDA and different values are being received (sets [MSR\[ALF\]](#)).
- NACK is detected when transmitting data, and [MCFGR1\[IGNACK\]](#) is clear (sets [MSR\[NDF\]](#)).
- NACK is detected and is expecting ACK for the address byte, and [MCFGR1\[IGNACK\]](#) is clear (sets [MSR\[NDF\]](#)).
- ACK is detected and is expecting NACK for the address byte, and [MCFGR1\[IGNACK\]](#) is clear (sets [MSR\[NDF\]](#)).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets [MSR\[FEF\]](#)).
- SCL (or SDA if [MCFGR1\[TIMECFG\]](#) is set) is low for ([MCFGR2\[TIMELOW\]](#) \* 256) prescaler cycles without a pin transition (sets [MSR\[PLTF\]](#)).

Software must respond to the [MSR\[PLTF\]](#) flag to terminate the existing command either cleanly (by clearing [MCR\[MEN\]](#)), or abruptly (by setting [MCR\[RST\]](#)).

The [MCFGR2\[BUSIDLE\]](#) field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

#### 47.3.1.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the [MCFGR1\[IGNACK\]](#) bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This configures the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

#### 47.3.2 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

### 47.3.2.1 Address Matching

The LPI2C slave can be configured:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- To match a range of addresses in either 7-bit or 10-bit addressing modes
- To match the General Call Address, and generate appropriate flags
- To match the SMBus Alert Address, and generate appropriate flags
- To detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave automatically performs slave-transmit or slave-receive transfers until:

- A NACK is detected (unless [MCFGR1\[IGNACK\]](#) is set)
- A bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- A (repeated) START or STOP condition is detected

### 47.3.2.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and [SCFGR1\[RXCFG\] = 1](#)).
- The Address Status register should only be read when the Address Valid flag is set.

### 47.3.2.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.

- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching extends for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

#### 47.3.2.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when **SCR[FILTEN]** is clear, when **SCR[FILTDZ]** is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

#### 47.3.2.5 Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag sets when the LPI2C slave is driving SDA, but samples a different value than what is expected.

- FIFO error flag sets due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag also sets due to an address overrun when [SCFGR1\[RXCFG\]](#) is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

### 47.3.3 Low power modes

**Table 47-6. LPI2C low power modes**

Mode	LPI2C Operation
Run	Normal operations
Stop	Can continue operating in stop mode if the Doze Enable bit is clear ( <a href="#">MCR[DOZEN]</a> = 0) and LPI2C uses an external or internal clock source that remains operating during stop mode.

### 47.3.4 Debug mode

**Table 47-7. LPI2C Debug mode**

Mode	LPI2C Operation
Debug	Can continue operating in Debug mode if the Debug Enable bit is set ( <a href="#">MCR[DBGEN]</a> = 1).

### 47.3.5 Interrupts and DMA requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The LPI2C master and slave interrupts may be combined
- The LPI2C master and slave transmit DMA requests may be combined
- The LPI2C master and slave receive DMA requests may be combined

### 47.3.5.1 Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

**Table 47-8. Master Interrupts and DMA Requests**

Master Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark <b>MFCR[TXWATER]</b>	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark <b>MFCR[RXWATER]</b>	Y	RX	Y
EPF	End Packet Flag	Master has transmitted a Repeated START or STOP condition	Y	N	Y
SDF	STOP Detect Flag	Master has transmitted a STOP condition	Y	N	Y
NDF	NACK Detect Flag	<ul style="list-style-type: none"> <li>During an address byte, the master expected an ACK but detected a NACK</li> <li>During an address byte, the master expected a NACK but detected an ACK</li> <li>During a master-transmitter data byte, the master detected a NACK</li> </ul>	Y	N	Y
ALF	Arbitration Lost Flag	<ul style="list-style-type: none"> <li>The master lost arbitration due to a START/STOP condition detected at the wrong time</li> <li>Or the master was transmitting data but received different data than the data that was transmitted</li> </ul>	Y	N	Y
FEF	FIFO Error Flag	The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout	Y	N	Y
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry	Y	N	Y
MBF	Master Busy Flag	LPI2C master is busy transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C master is enabled and activity is detected on the I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.	N	N	N

### 47.3.5.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

**Table 47-9. Slave Interrupts and DMA Requests**

Slave Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to the <a href="#">Slave Transmit Data (STDR)</a>	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the <a href="#">Slave Receive Data (SRDR)</a>	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the <a href="#">Slave Address Status (SASR)</a>	Y	RX	Y
TAF	Transmit ACK Flag	ACK/NACK can be written to the <a href="#">Slave Transmit ACK (STAR)</a>	Y	N	Y
RSF	Repeated Start Flag	Slave has detected an address match followed by a Repeated START condition	Y	N	Y
SDF	STOP Detect Flag	Slave has detected an address match followed by a STOP condition	Y	N	Y
BEF	Bit Error Flag	Slave was transmitting data, but received different data than what was transmitted	Y	N	Y
FEF	FIFO Error Flag	<ul style="list-style-type: none"> <li>• Transmit data underrun</li> <li>• Receive data overrun</li> <li>• Address status overrun (when Receive Data Configuration <a href="#">SCFGR1[RXCFG]</a> = 1).</li> </ul> FEF flag can only set when clock stretching is disabled.	Y	N	Y
AM0F	Address Match 0 Flag	Slave detected an address match with <a href="#">SAMR[ADDR0]</a> field	Y	N	N
AM1F	Address Match 1 Flag	Slave detected an address match with <a href="#">SAMR[ADDR1]</a> field or using an address range	Y	N	N
GCF	General Call Flag	Slave detected an address match with the General Call address	Y	N	N
SARF	SMBus Alert Response Flag	Slave detected an address match with the SMBus Alert address	Y	N	N
SBF	Slave Busy Flag	LPI2C slave is busy receiving an address byte or is transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected	N	N	N

## 47.3.6 Clocks

**Table 47-10. LPI2C clocks**

LPI2C Functional clock	The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.
External clock	The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled.  <b>NOTE:</b> The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.

For device-specific clocking information, refer to the Clocking chapter.

## 47.3.7 Resets

**Table 47-11. LPI2C Resets**

Chip reset	The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.
Software reset	<ul style="list-style-type: none"> <li>The LPI2C master implements a software reset bit in its Control Register. The <a href="#">MCR[RST]</a> bit resets all master logic and registers to their default state, except for the MCR register itself.</li> <li>The LPI2C slave implements a software reset bit in its Control Register. The <a href="#">SCR[RST]</a> bit resets all slave logic and registers to their default state, except for the SCR register itself.</li> </ul>
FIFO reset	<ul style="list-style-type: none"> <li>The LPI2C master implements write-only control bits that reset the transmit FIFO (<a href="#">MCR[RTF]</a>) and receive FIFO (<a href="#">MCR[RRF]</a>). After a FIFO is reset, that FIFO is empty.</li> <li>The LPI2C slave implements write-only control bits that reset the transmit data register (<a href="#">SCR[RTF]</a>) and receive data register (<a href="#">SCR[RRF]</a>). After a data register is reset, that data register is empty.</li> </ul>

### 47.3.8 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

**Table 47-12. LPI2C Triggers**

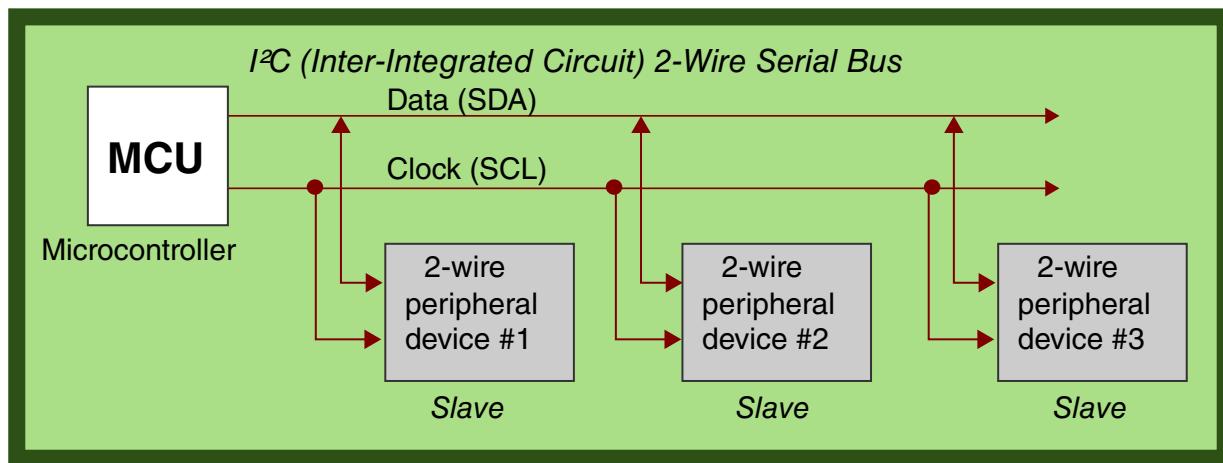

Trigger	Description
Master Output Trigger	The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.
Slave Output Trigger	The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.
Input Trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

## 47.4 Signal descriptions

**Table 47-13. Signals**

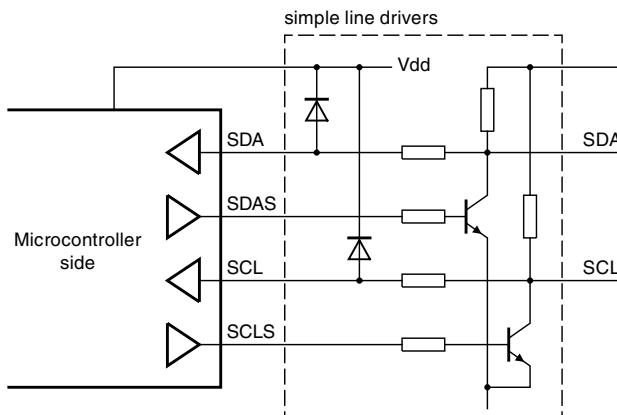

Signal	Name	2-Wire Scheme	4-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In 4-wire mode, this is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In 4-wire mode, this is the SDA input pin.	I/O
SCLS	Secondary I2C clock line	Not used	In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SCL pin.	I/O
SDAS	Secondary I2C data line	Not used	In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SDA pin.	I/O
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it initiates an LPI2C master transfer. HREQ is an additional pin separate from the 2-wire or 4-wire scheme.		I

The I<sup>2</sup>C 2-wire serial bus diagram shows the 2 signal connection.

**Figure 47-2. I<sup>2</sup>C 2-wire serial bus**

The I<sup>2</sup>C 4-wire serial bus diagram shows a possible 4 signal connection.

**Figure 47-3. I<sup>2</sup>C 4-wire serial bus**

## 47.5 Memory Map and Registers

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 47.5.1.4.4 Fields

Field	Function
31-10 —	Reserved
9	Reset Receive FIFO

Table continues on the next page...

## Memory Map and Registers

Field	Function
RRF	Resets the Receive FIFO. 0b - No effect 1b - Receive FIFO is reset
8 RTF	Reset Transmit FIFO Resets the Transmit FIFO. 0b - No effect 1b - Transmit FIFO is reset
7-4	Reserved
—	
3 DBGEN	Debug Enable Enables the Master in Debug mode. 0b - Master is disabled in debug mode 1b - Master is enabled in debug mode
2 DOZEN	Doze mode enable Enables or disables the master in Doze mode. 0b - Master is enabled in Doze mode 1b - Master is disabled in Doze mode
1 RST	Software Reset Resets all internal master logic and registers, except the <a href="#">Master Control (MCR)</a> register. RST remains set until cleared by software. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - Master logic is not reset 1b - Master logic is reset
0 MEN	Master Enable Enables the Master logic. 0b - Master logic is disabled 1b - Master logic is enabled

### 47.5.1.5 Master Status (MSR)

#### 47.5.1.5.1 Offset

Register	Offset
MSR	14h

#### 47.5.1.5.2 Function

MSR contains status flags for transmit and receive data; Start and Stop conditions; and bus and master busy or idle status.

### 47.5.1.5.3 Diagram

Bits	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

### 47.5.1.5.4 Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates that the I2C bus is busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 MBF	Master Busy Flag Indicates that the I2C Master is busy. 0b - I2C Master is idle 1b - I2C Master is busy
23-16 —	Reserved
15 —	Reserved
14 DMF	Data Match Flag Indicates that the received data has matched the <a href="#">MDMR[MATCH0]</a> and/or <a href="#">MDMR[MATCH1]</a> fields (as configured by <a href="#">MCFGR1[MATCFG]</a> ). Received data <i>that is discarded due to CMD field</i> does not cause DMF to set. 0b - Have not received matching data 1b - Have received matching data
13 PLTF	Pin Low Timeout Flag Sets when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, <a href="#">MCFGR3[PINLOW]</a> ), even when the LPI2C master is idle. <ul style="list-style-type: none"><li>Software is responsible for resolving the pin low condition.</li><li>PLTF cannot be cleared as long as the pin low timeout continues.</li><li>Before the LPI2C can initiate a START condition, the PLTF must be cleared.</li></ul> 0b - Pin low timeout has not occurred or is disabled 1b - Pin low timeout has occurred

Table continues on the next page...

## Memory Map and Registers

Field	Function
12 FEF	FIFO Error Flag  Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when <a href="#">MCFGR1[AUTOSTOP]</a> = 1. When FEF is set, the LPI2C master sends a STOP condition (if busy), and does not initiate a new START condition until FEF has been cleared. 0b - No error 1b - Master sending or receiving data without a START condition
11 ALF	Arbitration Lost Flag  Set if either of these conditions exist: <ul style="list-style-type: none"><li>• The LPI2C master transmits a logic one and detects a logic zero on the I2C bus</li><li>• The LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data</li></ul> When ALF sets, the LPI2C master releases the I2C bus (goes idle), and the LPI2C master does not initiate a new START condition until the ALF has been cleared. 0b - Master has not lost arbitration 1b - Master has lost arbitration
10 NDF	NACK Detect Flag  Set if the LPI2C master detects a NACK it was not expecting when transmitting an address or data. When set, the master does not initiate a new START condition until NDF has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NDF sets if a NACK is not generated.  When NDF is set, the LPI2C master automatically transmits a STOP condition if <a href="#">MCFGR1[AUTOSTOP]</a> = 1, or the transmit FIFO is not empty. 0b - Unexpected NACK was not detected 1b - Unexpected NACK was detected
9 SDF	STOP Detect Flag  Set when the LPI2C master generates a STOP condition. 0b - Master has not generated a STOP condition 1b - Master has generated a STOP condition
8 EPF	End Packet Flag  Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition. 0b - Master has not generated a STOP or Repeated START condition 1b - Master has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag  RDF sets whenever the number of words in the receive FIFO is greater than <a href="#">MFCR[RXWATER]</a> . 0b - Receive Data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag  TDF sets whenever the number of words in the transmit FIFO is equal or less than <a href="#">MFCR[TXWATER]</a> . 0b - Transmit data is not requested 1b - Transmit data is requested

## 47.5.1.6 Master Interrupt Enable (MIER)

### 47.5.1.6.1 Offset

Register	Offset
MIER	18h

### 47.5.1.6.2 Function

MIER contains transmit and receive data interrupt enables; Start, Stop, and Nack detect interrupt enables; and DMA interrupt enables.

### 47.5.1.6.3 Diagram

Bits	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

### 47.5.1.8.4 Fields

Field	Function
31-18	Reserved
—	
17-16	Reserved
—	
15-10	Reserved
—	
9	Receive Data Match Only
RDMO	When enabled, all received data that does not cause the Data Match Flag ( <a href="#">MSR[DMF]</a> ) to set is discarded. After <a href="#">MSR[DMF]</a> is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing <a href="#">MSR[DMF]</a> , to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless the the Data Match Flag ( <a href="#">MSR[DMF]</a> ) is set
8	Circular FIFO Enable
CIRFI	When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO empties as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This causes the contents of the transmit FIFO to be cycled through repeatedly. If <a href="#">MCFG1[AUTOSTOP]</a> is set, then a STOP condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-4	Reserved
—	
3	Reserved
—	
2	Host Request Select
HRSEL	Selects the source of the host request input. When host request is enabled, HRSEL should remain static (the Host Request Select should not change). 0b - Host request input is pin HREQ 1b - Host request input is input trigger

Table continues on the next page...

Field	Function
1 HRPOL	Host Request Polarity Configures the polarity of the host request pin. When host request is enabled, HRPOL should remain static (Host Request Polarity should not change). 0b - Active low 1b - Active high
0 HREN	Host Request Enable When enabled, the LPI2C master only initiates a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request. 0b - Host request input is disabled 1b - Host request input is enabled

## 47.5.1.9 Master Configuration 1 (MCFGR1)

### 47.5.1.9.1 Offset

Register	Offset
MCFGR1	24h

### 47.5.1.9.2 Function

The MCFGR1 should only be written when the I2C Master is disabled.

#### 47.5.1.13.4 Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master for these conditions: <ul style="list-style-type: none"><li>• Hold time for a START</li></ul>

*Table continues on the next page...*

## Memory Map and Registers

Field	Function
	<ul style="list-style-type: none"> <li>Setup and hold time for a repeated START</li> <li>Setup time for a STOP</li> </ul> <p>The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to <math>(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}</math> cycles.</p>
15-14 —	Reserved
13-8 CLKHI	<p>Clock High Period</p> <p>Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to <math>(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}</math> cycles.</p>
7-6 —	Reserved
5-0 CLKLO	<p>Clock Low Period</p> <p>Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to <math>(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}</math> cycles.</p>

### 47.5.1.14 Master Clock Configuration 1 (MCCR1)

#### 47.5.1.14.1 Offset

Register	Offset
MCCR1	50h

#### 47.5.1.14.2 Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by [Master Clock Configuration 0 \(MCCR0\)](#)), before switching to high speed mode (with timing configured by MCCR1).

### 47.5.1.14.3 Diagram

### 47.5.1.14.4 Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. The DATAVD must be configured to be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master for these conditions: <ul style="list-style-type: none"> <li>• Hold time for a START condition</li> <li>• Setup and hold time for a repeated START condition</li> <li>• Setup time for a STOP condition</li> </ul> The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to $(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}$ cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to $(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}$ cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The CLKLO value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to $(2 + \text{FILTSCL}) / 2^{\text{PRESCALE}}$ cycles.

## 47.5.1.15 Master FIFO Control (MFCR)

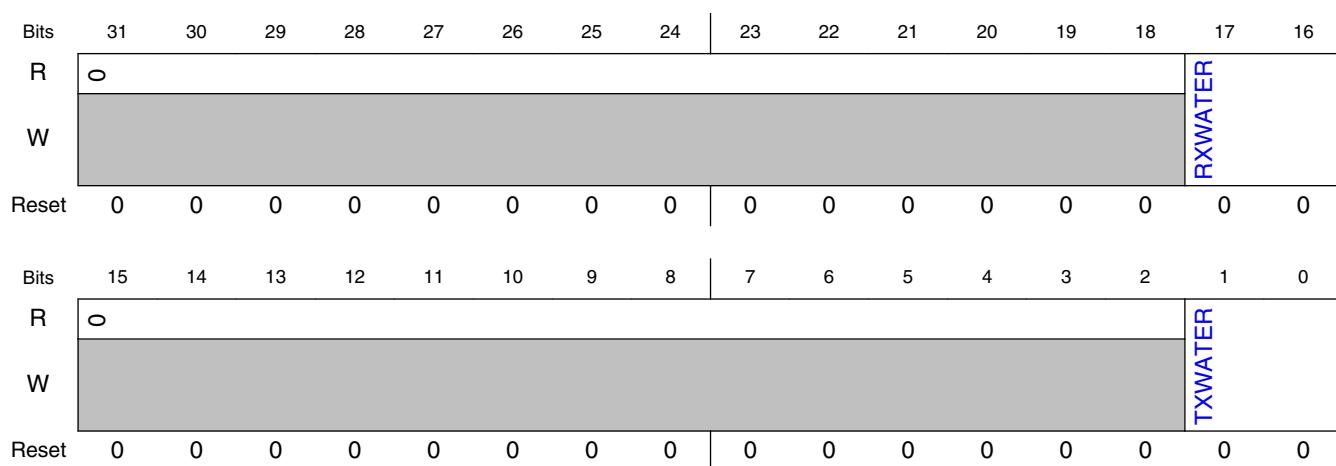

### 47.5.1.15.1 Offset

Register	Offset
MFCR	58h

### 47.5.1.15.2 Function

The Master FIFO control register is only used in Stop mode when the MFCR register is static (i.e., the MFCR register is not changing).

### 47.5.1.15.3 Diagram

### 47.5.1.15.4 Fields

Field	Function
31-18	Reserved
—	
17-16	Receive FIFO Watermark
RXWATER	The Receive Data Flag ( <a href="#">SSR[RDF]</a> ) is set whenever the number of words in the receive FIFO is greater than RXWATER. Writing a value equal to or greater than the FIFO size truncates the value.
15-2	Reserved
—	
1-0	Transmit FIFO Watermark

Field	Function
TXWATER	The Transmit Data Flag ( <a href="#">SSR[TDF]</a> ) is set whenever the number of words in the transmit FIFO is equal or less than TXWATER. Writing a value equal to or greater than the FIFO size truncates the value.

### 47.5.1.16 Master FIFO Status (MFSR)

#### 47.5.1.16.1 Offset

Register	Offset
MFSR	5Ch

#### 47.5.1.16.2 Function

MFSR gives the number of words in the transmit and receive FIFO.

#### 47.5.1.16.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### 47.5.1.16.4 Fields

Field	Function
31-19 —	Reserved
18-16 <a href="#">RXCOUNT</a>	Receive FIFO Count Returns the number of words in the receive FIFO.
15-3 —	Reserved
2-0 <a href="#">TXCOUNT</a>	Transmit FIFO Count Returns the number of words in the transmit FIFO.

## 47.5.1.17 Master Transmit Data (MTDR)

### 47.5.1.17.1 Offset

Register	Offset
MTDR	60h

### 47.5.1.17.2 Function

- An 8-bit write to the CMD field is ignored and does not increment the FIFO write pointer.
- An 8-bit write to the DATA field zero-extends the CMD field and increments the FIFO write pointer.
- A 16-bit or 32-bit writes both the CMD and DATA fields and increments the FIFO write pointer.

### 47.5.1.17.3 Diagram

### 47.5.1.17.4 Fields

Field	Function
31-11 —	Reserved
10-8 CMD	Command Data 000b - Transmit DATA[7:0] 001b - Receive (DATA[7:0] + 1) bytes 010b - Generate STOP condition 011b - Receive and discard (DATA[7:0] + 1) bytes

Table continues on the next page...

Field	Function
	100b - Generate (repeated) START and transmit address in DATA[7:0] 101b - Generate (repeated) START and transmit address in DATA[7:0]. This transfer expects a NACK to be returned. 110b - Generate (repeated) START and transmit address in DATA[7:0] using high speed mode 111b - Generate (repeated) START and transmit address in DATA[7:0] using high speed mode. This transfer expects a NACK to be returned.
7-0 DATA	Transmit Data Performing an 8-bit write to DATA zero-extends the CMD field.

### 47.5.1.18 Master Receive Data (MRDR)

#### 47.5.1.18.1 Offset

Register	Offset
MRDR	70h

#### 47.5.1.18.2 Function

Reading the Receive Data register returns the data received by the I2C master that has not been discarded.

#### 47.5.1.18.3 Diagram

### 47.5.1.19.4 Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the receive FIFO to be empty. 0b - No effect 1b - Receive Data Register is now empty
8 RTF	Reset Transmit FIFO Resets the transmit FIFO to be empty. 0b - No effect 1b - Transmit Data Register is now empty
7-6 —	Reserved
5 FILTDZ	Filter Doze Enable FILTDZ should only be updated when the I2C Slave is disabled. 0b - Filter remains enabled in Doze mode 1b - Filter is disabled in Doze mode
4 FILTEN	Filter Enable FILTEN should only be updated when the I2C Slave is disabled. 0b - Disable digital filter and output delay counter for slave mode 1b - Enable digital filter and output delay counter for slave mode
3-2 —	Reserved
1 RST	Software Reset The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - Slave mode logic is not reset 1b - Slave mode logic is reset
0 SEN	Slave Enable Enables the I2C Slave mode. 0b - I2C Slave mode is disabled 1b - I2C Slave mode is enabled

### 47.5.1.20 Slave Status (SSR)

#### 47.5.1.20.1 Offset

Register	Offset
SSR	114h

### 47.5.1.20.2 Function

SSR contains status flags for transmit and receive data; error conditions; and bus and slave busy or idle status.

### 47.5.1.20.3 Diagram

### 47.5.1.20.4 Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates if an I2C bus is idle or busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 SBF	Slave Busy Flag Indicates if an I2C slave is idle or busy. 0b - I2C Slave is idle 1b - I2C Slave is busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag <ul style="list-style-type: none"> <li>SARF is cleared by reading the <a href="#">Slave Address Status (SASR)</a> register</li> <li>SARF cannot generate an asynchronous wakeup</li> </ul> 0b - SMBus Alert Response is disabled or not detected 1b - SMBus Alert Response is enabled and detected
14 GCF	General Call Flag Indicates whether a slave has detected the General Call Address.

*Table continues on the next page...*

Field	Function
	<ul style="list-style-type: none"> <li>General Call Flag is cleared by reading the <a href="#">Slave Address Status (SASR)</a> register</li> <li>General Call Flag cannot generate an asynchronous wakeup</li> </ul> <p>0b - Slave has not detected the General Call Address or the General Call Address is disabled 1b - Slave has detected the General Call Address</p>
13 AM1F	<p>Address Match 1 Flag</p> <p>Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by <a href="#">SCFGR1[ADDRCFG]</a>.</p> <ul style="list-style-type: none"> <li>Address Match 1 Flag is cleared by reading the <a href="#">Slave Address Status (SASR)</a> register</li> <li>Address Match 1 Flag cannot generate an asynchronous wakeup</li> </ul> <p>0b - Have not received an ADDR1 or ADDR0/ADDR1 range matching address 1b - Have received an ADDR1 or ADDR0/ADDR1 range matching address</p>
12 AM0F	<p>Address Match 0 Flag</p> <p>Indicates that the received address has matched the ADDR0 field as configured by <a href="#">SCFGR1[ADDRCFG]</a>.</p> <ul style="list-style-type: none"> <li>AM0F is cleared by reading the <a href="#">Slave Address Status (SASR)</a> register</li> <li>AM0F cannot generate an asynchronous wakeup</li> </ul> <p>0b - Have not received an ADDR0 matching address 1b - Have received an ADDR0 matching address</p>
11 FEF	<p>FIFO Error Flag</p> <p>FEF can only be set when clock stretching is disabled.</p> <p>0b - FIFO underflow or overflow was not detected 1b - FIFO underflow or overflow was detected</p>
10 BEF	<p>Bit Error Flag</p> <p>BEF sets if the LPI2C slave transmits a logic one and detects a logic zero on the I2C bus. The slave ignores the rest of the transfer until the next (repeated) START condition.</p> <p>0b - Slave has not detected a bit error 1b - Slave has detected a bit error</p>
9 SDF	<p>STOP Detect Flag</p> <p>SDF sets when the LPI2C slave detects a STOP condition and if the LPI2C slave matched the last address byte.</p> <p>0b - Slave has not detected a STOP condition 1b - Slave has detected a STOP condition</p>
8 RSF	<p>Repeated Start Flag</p> <p>RSF sets when the LPI2C slave detects a repeated START condition and if the LPI2C slave matched the last address byte. The RSF does not set when the slave first detects a START condition.</p> <p>0b - Slave has not detected a Repeated START condition 1b - Slave has detected a Repeated START condition</p>
7-4 —	Reserved
3 TAF	<p>Transmit ACK Flag</p> <p>TAF is cleared by writing to the <a href="#">Slave Transmit ACK (STAR)</a> register.</p> <p>0b - Transmit ACK/NACK is not required 1b - Transmit ACK/NACK is required</p>
2 AVF	<p>Address Valid Flag</p> <p>AVF is cleared by reading the <a href="#">Slave Address Status (SASR)</a> register. When <a href="#">SCFGR1[RXCFG] = 1</a>, <a href="#">SSR[AVF]</a> is also cleared by reading the <a href="#">Slave Receive Data (SRDR)</a> register.</p> <p>0b - Address Status Register is not valid</p>

*Table continues on the next page...*

## Memory Map and Registers

Field	Function
1 RDF	1b - Address Status Register is valid  Receive Data Flag  RDF is cleared by reading the <a href="#">Slave Receive Data (SRDR)</a> register. When <a href="#">SCFGR1[RXCFG]</a> = 1, RDF is not cleared when reading the <a href="#">Slave Receive Data (SRDR)</a> register and if <a href="#">SSR[AVF]</a> is set. 0b - Receive data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag  TDF is cleared by writing the to the <a href="#">Slave Transmit Data (STDR)</a> register. When <a href="#">SCFGR1[TXCFG]</a> = 0 and if a NACK or a Repeated START or STOP condition is detected, then TDF is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

### 47.5.1.21 Slave Interrupt Enable (SIER)

#### 47.5.1.21.1 Offset

Register	Offset
SIER	118h

#### 47.5.1.21.2 Function

SIER contains transmit and receive data interrupt enables; Start and Stop detect interrupt enables; and other slave interrupt enables.

#### 47.5.1.21.3 Diagram

10 TXCFG	<p>Transmit Flag Configuration</p> <p>The transmit data flag always asserts before a NACK is detected at the end of a slave-transmit transfer. This can cause an extra word to be written to the transmit data FIFO.</p> <ul style="list-style-type: none"> <li>• When TXCFG = 0, the Transmit Data register is automatically emptied when a slave-transmit transfer is detected. This causes the transmit data flag to assert whenever a slave-transmit transfer is detected, and causes the transmit data flag to negate at the end of the slave-transmit transfer.</li> <li>• When TXCFG = 1, the Transmit Data flag asserts whenever the Transmit Data register is empty, and the Transmit Data flag negates when the Transmit Data register is full. This allows the Transmit Data register to be filled before a slave-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a slave transmit transfer.</li> </ul>

Table continues on the next page...

Field	Function
	0b - Transmit Data Flag only asserts during a slave-transmit transfer when the Transmit Data register is empty 1b - Transmit Data Flag asserts whenever the Transmit Data register is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disables match on SMBus Alert 1b - Enables match on SMBus Alert
8 GCEN	General Call Enable Enables a general call address. 0b - General Call address is disabled 1b - General Call address is enabled
7-5 —	Reserved
4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during slave-transmit address byte(s) and slave-receiver address and data byte(s), to allow software to write the <a href="#">Slave Transmit ACK (STAR)</a> register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the 9th bit, and is therefore not compatible with high speed mode.  When ACKSTALL is enabled, there is no need to set either RX SCL Stall ( <a href="#">SCFGR1[RXSTALL]</a> ) or Address SCL Stall ( <a href="#">SCFGR1[ADRSTALL]</a> ). 0b - Clock stretching is disabled 1b - Clock stretching is enabled
2 TXDSTALL	TX Data SCL Stall Enables SCL clock stretching when the <a href="#">SSR[TDF]</a> = 1 during a slave-transmit transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when <a href="#">SSR[RDF]</a> = 1 during a slave-receive transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when <a href="#">SSR[AVF]</a> = 1. Clock stretching only occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled

0 TXNACK	<p>Transmit NACK</p> <p>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK.</p> <ul style="list-style-type: none"> <li>When <a href="#">SCFGR1[ACKSTALL]</a> is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that stalls the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).</li> <li>To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.</li> </ul> <p>0b - Write a Transmit ACK for each received word 1b - Write a Transmit NACK for each received word</p>

## 47.5.1.28 Slave Transmit Data (STDR)

### 47.5.1.28.1 Offset

Register	Offset
STDR	160h

### 47.5.1.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The [SCFGR1\[TXDSTALL\]](#) bit enables clock stretching during the 1st data bit of a slave-transmit transfer.

- If clock stretching is enabled ([SCFGR1\[TXDSTALL\]](#) = 1), then the transmit data transfer is stalled until the STDR is updated. Clock stretching is extended by at least 1 bus clock cycle after STDR is updated, and clock stretching can be delayed even more using the Clock Hold Time field ([SCFGR2\[CLKHOLD\]](#)).
- If clock stretching is disabled ([SCFGR1\[TXDSTALL\]](#) = 0), then the transmit data should be written before the start of the slave-transmit transfer; otherwise (that is, if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag ([SSR\[FEF\]](#)) sets.

#### NOTE

The output trigger in "Peripheral Triggers" section is not applicable for this device.

### 48.2 Overview

LPSPI is a low-power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus, either as a master and/or as a slave. The SPI bus is a synchronous serial communication interface used in embedded systems, typically to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

## 48.2.1 Block diagram

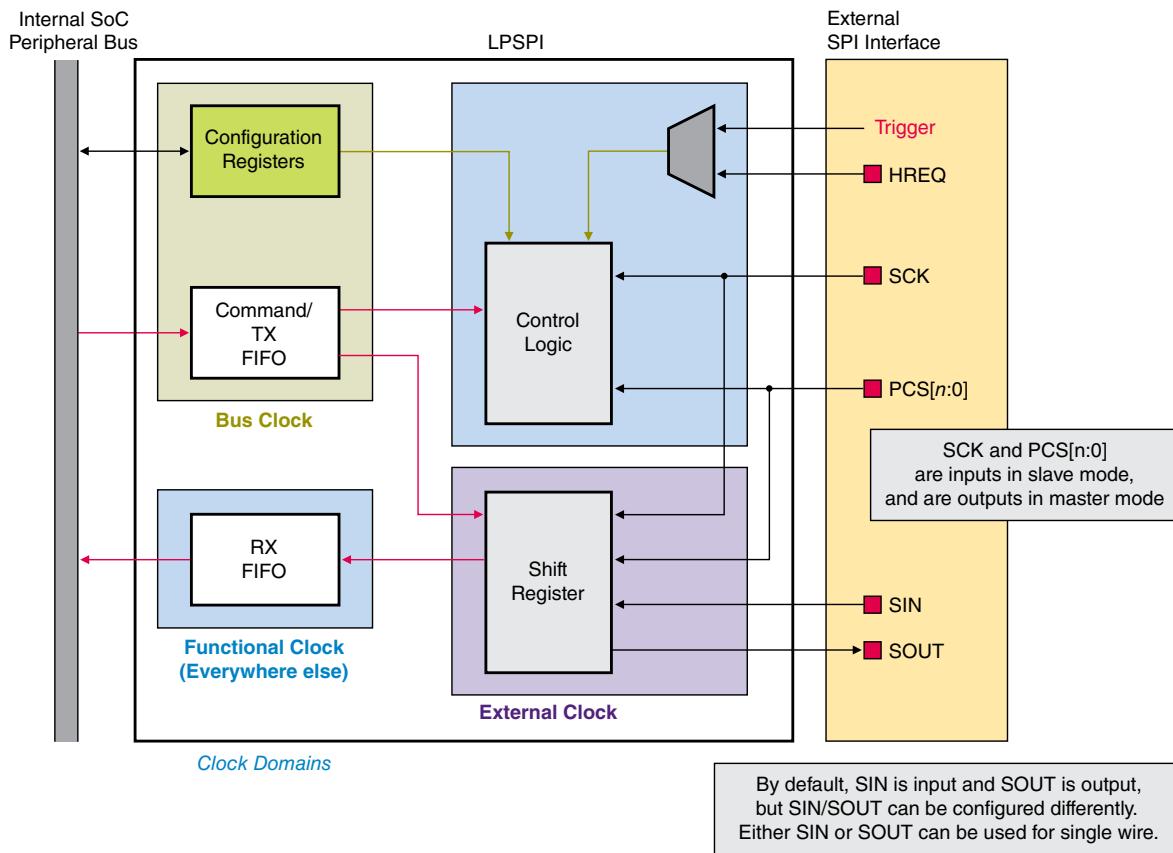

Figure 48-1. Block diagram

## 48.2.2 Features

LPSPI supports:

- Uses little CPU overhead, with DMA offloading of FIFO register accesses
- Continues operating in stop modes, if configured to do so and an appropriate clock is available
- Supports DMA accesses and generates a DMA request
- Word size of 32 bits
- Configurable clock polarity and clock phase
- Master operation supporting up to 4 peripheral chip selects
- Slave operation
- Command/transmit FIFO of 16 words
- Receive FIFO of 16 words
- Flexible timing parameters in Master mode, including SCK frequency and delays between PCS and SCK edges

- Full duplex transfers supporting 1-bit transmit and receive on each clock edge
- Half duplex transfers supporting 1-bit transmit or receive on each clock edge
- Half duplex transfers supporting 2-bit transmit or receive on each clock edge (master only)
- Half duplex transfers supporting 4-bit transmit or receive on each clock edge (master only)
- Host request can be used to control the start of a SPI bus transfer (master only)
- Receive data match logic supporting wakeup on data match

## 48.3 Functional description

### 48.3.1 Master mode

#### 48.3.1.1 Transmit and Command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- Transmit data words are stored to the transmit/command FIFO, by writing the [Transmit Data \(TDR\)](#).
- Command words are stored to the transmit/command FIFO, by writing the [Transmit Command \(TCR\)](#).

When a command word is at the top of the transmit/command FIFO, the actions that can occur depend upon whether the LPSPI module is either busy or between frames. See [Continuous Transfer bit, TCR\[CONT\]](#) and [Continuing Command bit, TCR\[CONTC\]](#)

**Table 48-2. Possible actions when a command word is at the top of the transmit/command FIFO**

Condition	Action
If LPSPI is between frames	then the command word is pulled from the FIFO, and that command word controls all subsequent transfers.
If LPSPI is busy and the Continuing Command bit (TCR[CONTC]) is cleared	then the SPI frame completes at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates (stop) the existing transfer regardless of the previous TCR[CONT] value.
If LPSPI is busy and the existing TCR[CONT] bit is set and the new TCR[CONTC] value is set	then the command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ configuration), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word).

**Table 48-2. Possible actions when a command word is at the top of the transmit/command FIFO**

Condition	Action
	When TCR[CONT] is set, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. Essentially the TCR[CONT] bit is ignored when not at a frame boundary, so the frame ends prematurely.

About [TCR\[CONT\]](#) and [TCR\[CONTC\]](#) :

- TCR[CONT] = 1 is used to keep PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONT] = 1 is used to indicate that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONT] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary, is when the previous command has TCR[CONT] = 1.

The current state of the existing command word is read from [Transmit Command \(TCR\)](#). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO) and LPSPI must be enabled ([CR\[MEN\]](#) bit is set).

Writing the TCR does not initiate a SPI bus transfer, unless the [TCR\[TXMSK\]](#) = 1.

When the TCR[TXMSK] bit is set, a new command word is not be loaded until the end of the existing frame (based on FRAMESZ configuration); at the end of the transfer, the TCR[TXMSK] bit clears.

In master mode, the LPSPI command word in TCR controls SPI attributes (using bits and fields in registers).

**Table 48-3. LPSPI Command Word in Master mode**

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock Polarity	Configures the polarity of the SCK pin. Any change of CPOL value will cause a transition on the SCK pin.	N
CPHA	Clock Phase	Configures the clock phase of the transfer.	N
PRESCALE	Prescaler Value	Configures a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N

*Table continues on the next page...*

**Table 48-3. LPSPI Command Word in Master mode (continued)**

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
PCS	Peripheral Chip Select	Configures which PCS asserts for the transfer; the polarity of PCS is static and configured by <a href="#">CFG1[PCSPOL]</a> . If <a href="#">CFG1[PCSCFG]</a> = 1, then PCS[3:2] should not be selected.	N
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous Transfer	Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y
CONTC	Continuing Command	Indicates that this is a new command word for the existing continuous transfer. The CONTC bit when set must only be written to the transmit/command FIFO on a frame boundary.	Y
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.	Y
TXMSK	Transmit Data Mask	Masks the transmit data, so that masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by <a href="#">CFG1[OUTCFG]</a> ). Useful for half-duplex transfers.	Y
WIDTH	Transfer Width	Configures the number of bits shifted on each SCK pulse. <ul style="list-style-type: none"> <li>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</li> <li>• 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one bit (TCR[TXMSK] or TCR[RXMSK]) must also be set.</li> </ul>	Y
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). <ul style="list-style-type: none"> <li>• The minimum frame size is 8 bits.</li> <li>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</li> <li>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</li> <li>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</li> </ul>	Y

**SPI bus transfers:**

- LPSPI initiates a SPI bus transfer when all conditions are true:
  - Data is written to the transmit FIFO
  - And the HREQ pin is asserted (or the HREQ function is disabled)
  - And LPSPI is enabled

- To perform the SPI bus transfer, LPSPI uses the attributes configured in [Transmit Command \(TCR\)](#) and uses the timing parameters in [Clock Configuration \(CCR\)](#).
- The SPI bus transfer ends after the FRAMESZ configuration is reached, or at the end of a word when a new transmit command word is at the top of the transmit/command FIFO.
- The HREQ input is only checked on the next time that LPSPI goes idle (LPSPI completes the current transmit FIFO and there are no attribute updates in TCR).

**Circular FIFO:** The transmit/command FIFO also supports a Circular FIFO feature, which enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled ([CFGRO\[CIRFIFO\]](#) = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the transmit/command FIFO is considered empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

### 48.3.1.2 Receive FIFO and Data Match

The receive FIFO stores receive data during SPI bus transfers. When [TCR\[RXMSK\]](#) = 1, the receive data is discarded instead of being stored in the receive FIFO.

- The receive data is written to the receive FIFO at the end of the frame.
- During a multiple word or continuous transfer, the receive data is also written to the receive FIFO at the same time as the new transmit data is read from the transmit FIFO.
- During a continuous transfer, if the transmit FIFO is empty, then the receive data is only written to the receive FIFO after the transmit FIFO is written or after TCR is written to end the frame.

Receive data supports a receive data match function that can match received data against one of two words in the [DMR0](#) and [DMR1](#) registers or against a masked data word. The receive data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the [TCR\[RXMSK\]](#) bit cannot cause the data match to set, and delays the receive data match on the first received data word, until all discarded data is received.
- The receive data match function can also be configured to discard all received data until a data match is detected, using the [CFGRO\[RDMO\]](#) bit.
- After a receive data match, to allow all subsequent data to be received, clear the [CFGRO\[RDMO\]](#) bit, then clear the [SR\[DMF\]](#) bit.

### 48.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the [Clock Configuration \(CCR\)](#) cannot be changed when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, the [TCR\[PRESCALE\]](#) configuration can be changed between SPI bus transfers using the Transmit Command Register (TCR).

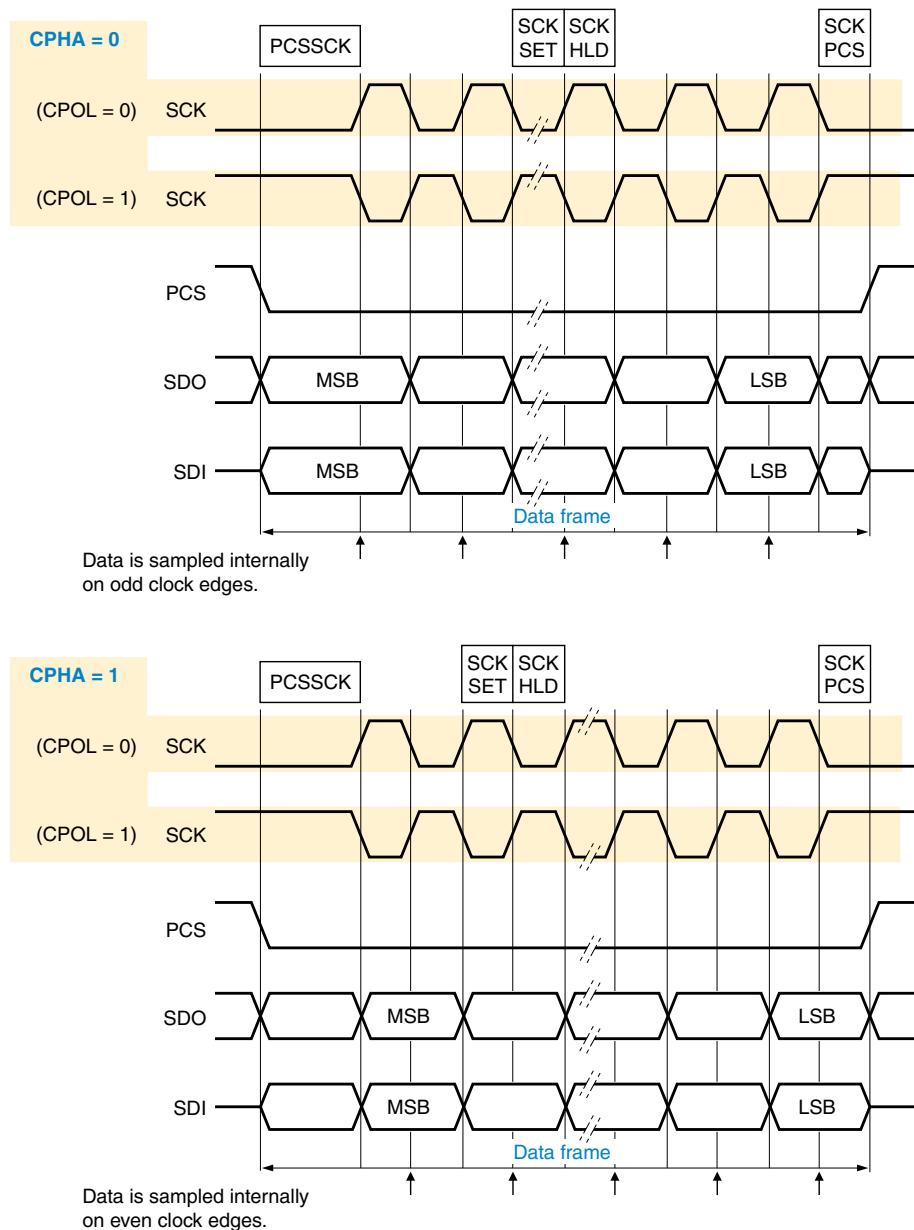

#### NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the datasheet specs based on the LPSPI functional clock frequency and prescaler value.

**Table 48-4. LPSPI timing parameters**

<a href="#">Clock Configuration (CCR)</a>		<a href="#">Description</a>	<a href="#">Min</a>	<a href="#">Max</a>
<a href="#">Field</a>	<a href="#">Name</a>			
SCKDIV	SCK Divider	Configures the SCK clock period to (SCKDIV + 2) cycles. When SCK Divider is configured to an odd number of cycles, the first half of the SCK cycle is one cycle longer than the second half of the SCK cycle.	0 (2 cycles)	255 (257 cycles)
DBT	Delay Between Transfers (PCS negation to PCS assertion)	Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT/2) + 1 cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (257 cycles)
DBT	Delay Between Transfers (last SCK edge to first SCK edge)	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)
PCSSCK	PCS-to-SCK Delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS Delay	Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by [TCR\[CPHA\]](#), [TCR\[CPOL\]](#), [CCR\[SCKPCS\]](#), and [CCR\[PCSSCK\]](#).

**Figure 48-2. Clock Phase (TCR[CPHA]) timing diagram example**

#### 48.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, the SIN and SOUT pins can be configured using [CFGRI1\[PINCFG\]](#).
- To determine if an output data pin (like SOUT) tristates when PCS is negated, or if the output data pin simply retains the last value, use [CFGRI1\[PCSCFG\]](#).
- When configuring for half-duplex transfers the output data pins must be configured to tristate when PCS is negated; use [CFGRI1\[OUTCFG\]](#) [CFGRI1\[OUTCFG\]](#).

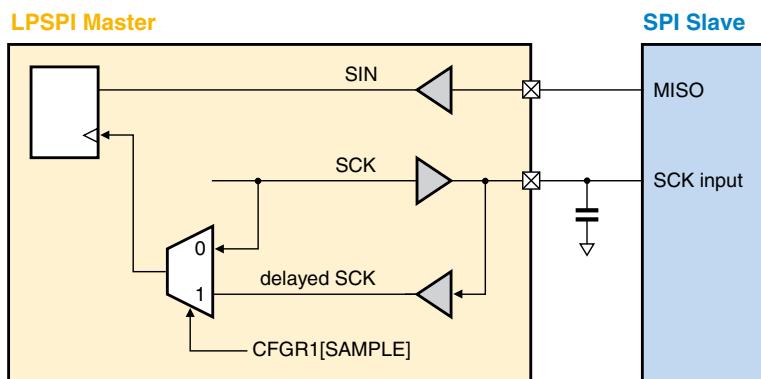

- When performing half-duplex 2-bit transfers, **CFG1[PCSCFG]** can be set to any value.
- When performing half-duplex 4-bit transfers, **CFG1[PCSCFG]** must equal 0x1.

### 48.3.1.5 Clock loopback

Configure the LPSPI master to use either the output clock or a loopback clock to sample the receive data (for example, SIN). Use one of these these clocks to sample the input data:

- The SCK output clock directly
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is configured by setting **CFG1[SAMPLE]**. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

**Figure 48-3. Clock loopback**

See the chip data sheet for the specific input setup time in master loopback mode.

### 48.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses
- Does not use the Clock Configuration Register (CCR)
- During SPI bus transfers, requires that the **Transmit Command (TCR)** register remain static (unchanging)

### 48.3.2.1 Transmit and Command FIFO commands

Before enabling LPSPI in slave mode, initialize the [Transmit Command \(TCR\)](#) register, although the TCR register does not update until after LPSPI is enabled. After being enabled, the TCR register should only be changed if LPSPI is idle. In slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

**Table 48-5. LPSPI Command Word in Slave mode**

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock Polarity	Configures the polarity of the external SCK input.
CPHA	Clock Phase	Configures the clock phase of transfer.
PRESCALE	Prescaler Value	Configures the LPSPI functional clock prescaler.
PCS	Peripheral Chip Select	Configures which PCS is used, the polarity of PCS is static and configured by <a href="#">CFG1[PCSPOL]</a> . If <a href="#">CFG1[PCSCFG]</a> is not equal to zero, then PCS[3:2] pins should not be selected.
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous Transfer	When Continuous Transfer is set in slave mode and after the first FRAMESZ bits are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there was a 32-bit shift register.
CONTC	Continuing Command	CONTC bit is reserved (in slave mode).
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.
TXMSK	Transmit Data Mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by <a href="#">CFG1[OUTCFG]</a> ). Useful for half-duplex transfers.
WIDTH	Transfer Width	Configures the number of bits shifted on each SCK pulse. <ul style="list-style-type: none"> <li>1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</li> </ul>
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). <ul style="list-style-type: none"> <li>The minimum frame size is 8 bits.</li> <li>The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</li> <li>If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</li> <li>If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</li> </ul>

### 48.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When **TCR[RXMSK]** = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the **DMR0** and **DMR1** registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because **TCR[RXMSK]** = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the **CFGR0[RDMO]** bit.
- After a receive data match, to allow all subsequent data to be received, first clear the **CFGR0[RDMO]** bit, then clear the **SR[DMF]** bit.

### 48.3.2.3 Clocked interface

The LPSPI module supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Using Clock Phase **TCR[CPHA]** = 1 (data is changed on the leading edge of SCK and captured on the following edge)
- Configuring the PCS input to be always asserted (**CFGR1[PCSPOLn]** = 1). For example, to configure PCS[0] to be always asserted, set PCSPOL[0] = 1, and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOLn] could be used to invert that value.
- Setting **CFGR1[AUTOPCS]** = 1 (Automatic PCS generation is enabled). When **CFGR1[AUTOPCS]** = 1, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last SCK edge of one word and the first SCK edge of the next word.

### 48.3.3 Low power modes

**Table 48-6. Low power modes**

Chip mode	LPSPI operation
Run	Normal operation
Stop	Can continue operating in stop mode if <b>CR[DOZEN]</b> = 0 and LPSPI is using an external or internal clock source that remains operating during stop mode.

### 48.3.4 Debug mode

**Table 48-7. Debug mode**

Chip mode	LPSPI operation
Debug (the core is in Debug/Halted mode)	Can continue operating in Debug mode, if the <a href="#">CR[DBGEN]</a> = 1.

### 48.3.5 Interrupts and DMA Requests

The next table lists the slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit/receive DMA requests.

**Table 48-8. LPSPI Interrupts and DMA Requests**

Status (SR)		Description	Can generate		
Status Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to transmit FIFO, as configured by the Transmit FIFO Watermark <a href="#">FCR[TXWATER]</a>	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the receive FIFO, as configured by the Receive FIFO Watermark <a href="#">FCR[RXWATER]</a>	Y	RX	Y
WCF	Word Complete Flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame Complete Flag	Frame is complete, and PCS has negated	Y	N	Y
TCF	Transfer Complete Flag	Transfer is complete, PCS has negated, and the transmit/command FIFO is empty	Y	N	Y
TEF	Transmit Error Flag	Indicates a transmit/command FIFO underrun. In master mode when <a href="#">CFG1[NOSTALL]</a> = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag bit cannot set.	Y	N	Y
REF	Receive Error Flag	Receive error flag, indicates a receive FIFO overflow.	Y	N	Y
DMF	Data Match Flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module Busy Flag	LPSPI is busy performing a SPI bus transfer	N	N	N

### 48.3.6 Clocks

**Table 48-9. LPSPI Clocks**

LPSPI Functional clock	<ul style="list-style-type: none"> <li>The LPSPI functional clock is asynchronous to the bus clock.</li> <li>If the LPSPI functional clock remains enabled in low power modes, then LPSPI can perform SPI bus transfers and low power wakeups, in both master and slave modes.</li> <li>The LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).</li> </ul>
External clock	<ul style="list-style-type: none"> <li>The LPSPI shift register is clocked directly by the SCK clock.</li> <li>How the SCK clock is generated or supplied depends upon the mode (master or slave): <ul style="list-style-type: none"> <li>In master mode: the SCK clock is generated internally.</li> <li>In slave mode: the SCK clock is supplied externally.</li> </ul> </li> </ul>
Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

For chip-specific clocking information, see the Clocking chapter.

### 48.3.7 Resets

**Table 48-10. Resets**

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	<ul style="list-style-type: none"> <li>Resets the LPSPI logic and registers to their default state, except for the Control Register.</li> <li>The LPSPI software reset is in the Control Register <a href="#">CR[RST]</a>.</li> </ul>
FIFO resets	<ul style="list-style-type: none"> <li>Resets the transmit/command FIFO and the receive FIFO.</li> <li>The Reset Transmit FIFO field, <a href="#">CR[RTF]</a> and the Reset Receive FIFO field, <a href="#">CR[RRF]</a> are write-only bits.</li> <li>After being reset, a FIFO is empty.</li> </ul>

### 48.3.8 Peripheral Triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

**Table 48-11. LPSPI Triggers**

Trigger	Description	Notes
Frame Output Trigger	The frame output trigger is an idle high signal, which: <ul style="list-style-type: none"> <li>asserts at the end of each frame (when PCS negates)</li> <li>remains asserted until PCS next asserts</li> </ul>	LPSPI generates 2 output triggers that can be connected to other peripherals on the device.
Word Output Trigger	The word output trigger:	

*Table continues on the next page...*

**Table 48-11. LPSPI Triggers (continued)**

Trigger	Description	Notes
	<ul style="list-style-type: none"> <li>• asserts at the end of each received word</li> <li>• remains asserted for 1 SCK period</li> </ul>	
Input Trigger	<p>To control the start of a LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input.</p> <ul style="list-style-type: none"> <li>• The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected.</li> <li>• When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored.</li> <li>• Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.</li> </ul>	

## 48.4 Signal descriptions

**Table 48-12. Signals**

Signal	Name	Description	I/O
SCK	Serial clock	<ul style="list-style-type: none"> <li>• Input in slave mode</li> <li>• Output in master mode</li> </ul>	I/O
PCS[0]	Peripheral Chip Select	<ul style="list-style-type: none"> <li>• Input in slave mode</li> <li>• Output in master mode</li> </ul>	I/O
PCS[1] / HREQ	Peripheral Chip Select or Host Request	<p>Host Request pin is selected when <a href="#">CFG0[HREN]</a> = 1 and <a href="#">CFG0[HRSEL]</a> = 0</p> <ul style="list-style-type: none"> <li>• Input in either slave mode or when used as master Host Request</li> <li>• Output in master mode</li> </ul>	I/O
PCS[2] / DATA[2]	Peripheral Chip Select or data pin 2 during parallel data transfers	<p>When <a href="#">CFG1[PCSCFG]</a> = 0:</p> <ul style="list-style-type: none"> <li>• Input in slave mode</li> <li>• Output in master mode</li> </ul> <p>When <a href="#">CFG1[PCSCFG]</a> = 1:</p> <ul style="list-style-type: none"> <li>• Input in half-duplex parallel data receive transfers</li> <li>• Output in half-duplex parallel data transmit transfers</li> </ul>	I/O
PCS[3] / DATA[3]	Peripheral Chip Select or data pin 3 during parallel data transfers	<p>When <a href="#">CFG1[PCSCFG]</a> = 0:</p> <ul style="list-style-type: none"> <li>• Input in slave mode</li> <li>• Output in master mode</li> </ul> <p>When <a href="#">CFG1[PCSCFG]</a> = 1:</p> <ul style="list-style-type: none"> <li>• Input in half-duplex parallel data receive transfers</li> <li>• Output in half-duplex parallel data transmit transfers</li> </ul>	I/O
SOUT / DATA[0]	Serial Data Output	Can be configured as serial data input signal	I/O

Table continues on the next page...

**Table 48-12. Signals (continued)**

Signal	Name	Description	I/O
		<ul style="list-style-type: none"> <li>Used as data pin 0 in half-duplex parallel data transfers</li> </ul>	
SIN / DATA[1]	Serial Data Input	<p>Can be configured as serial data output signal</p> <ul style="list-style-type: none"> <li>Used as data pin 1 in half-duplex parallel data transfers</li> </ul>	I/O

## 48.5 Memory map and registers

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. LPSPI does not check if programmed values in the registers are correct, so application software must take care to write valid values only.

### 48.5.1 LPSPI register descriptions

### 48.5.1.5.4 Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag  In Master mode, MBF asserts when there is data to transmit and LPSPI is able to transmit (eg: HREQ asserted, etc). It negates after the PCS negates and the LPSPI master has waited half the DBT time with no new data to transmit. Slave mode asserts MBF when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag  Indicates that the received data has matched the <a href="#">DMR0[MATCH0]</a> and/or <a href="#">DMR1[MATCH1]</a> fields (as configured by <a href="#">CFG1[MATCFG]</a> ). 0b - Have not received matching data 1b - Have received matching data
12 REF	Receive Error Flag  The Receive Error Flag sets when the Receiver FIFO overflows. When the Receive Error Flag is set, it is recommended to first end the transfer, empty the Receive FIFO, clear the Receive Error Flag and then restart the transfer from the beginning. 0b - Receive FIFO has not overflowed 1b - Receive FIFO has overflowed
11 TEF	Transmit Error Flag  The Transmit Error Flag sets when the Transmit FIFO underruns. When the Transmit Error Flag is set, it is recommended to first end the transfer, clear the Transmit Error Flag and then restart the transfer from the beginning. 0b - Transmit FIFO underrun has not occurred 1b - Transmit FIFO underrun has occurred
10 TCF	Transfer Complete Flag  In Master mode when LPSPI returns to idle state with the transmit FIFO empty, the Transfer Complete Flag sets. 0b - All transfers have not completed

Table continues on the next page...

Field	Function
	1b - All transfers have completed
9 FCF	Frame Complete Flag The Frame Complete Flag sets at the end of each frame transfer, when the PCS negates. 0b - Frame transfer has not completed 1b - Frame transfer has completed
8 WCF	Word Complete Flag The Word Complete Flag sets when the last bit of a received word is sampled. 0b - Transfer of a received word has not yet completed 1b - Transfer of a received word has completed
7-2 —	Reserved
1 RDF	Receive Data Flag The Receive Data Flag is set whenever the number of words in the receive FIFO is greater than the value in <a href="#">FCR[RXWATER]</a> . 0b - Receive Data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag The Transmit Data Flag is set whenever the number of words in the transmit FIFO is equal or less than the value in <a href="#">FCR[TXWATER]</a> . 0b - Transmit data not requested 1b - Transmit data is requested

4-0	Transmit FIFO Count
TXCOUNT	Returns the number of words currently stored in the transmit FIFO.

### 48.5.1.15 Transmit Command (TCR)

#### 48.5.1.15.1 Offset

Register	Offset
TCR	60h

### 48.5.1.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register pushes the data into the transmit FIFO, in the order that the data are written. The Command Register should only be written using 32-bit writes. Command Register writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- In **Master mode**, writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware clears TXMSK when the PCS negates.
- In **Master mode**, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- In **Slave mode**, the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

#### 48.5.1.15.4 Fields

Field	Function
31 CPOL	Clock Polarity  The Clock Polarity field is only updated when PCS negated.  See <a href="#">Figure 48-2</a> .  0b - The inactive state value of SCK is low 1b - The inactive state value of SCK is high
30 CPHA	Clock Phase  The Clock Phase field is only updated when PCS negated.  See <a href="#">Figure 48-2</a> .  0b - Captured. Data is captured on the leading edge of SCK and <b>changed</b> on the following edge of SCK 1b - Changed. Data is changed on the leading edge of SCK and <b>captured</b> on the following edge of SCK
29-27 PRESCALE	Prescaler Value  For all SPI bus transfers, the Prescaler value applied to the clock configuration register. The Prescaler Value field is only updated when PCS negated. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select  Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated when PCS negated.  <b>NOTE:</b> The entire PCS field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2] 11b - Transfer using PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap  Byte swap swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Byte swap is disabled 1b - Byte swap is enabled
21	Continuous Transfer

Table continues on the next page...

## Memory map and registers

Field	Function
CONT	<ul style="list-style-type: none"> <li>In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame.</li> <li>In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation.</li> </ul> <p>0b - Continuous transfer is disabled 1b - Continuous transfer is enabled</p>
20 CONTC	<p>Continuing Command</p> <p>In Master mode, the CONTC bit allows the command word to be changed within a continuous transfer.</p> <ul style="list-style-type: none"> <li>The initial command word must enable continuous transfer (CONT = 1),</li> <li>the continuing command must set this bit (CONTC = 1),</li> <li>and the continuing command word must be loaded on a frame size boundary.</li> </ul> <p>For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary.</p> <p>0b - Command word for start of new transfer 1b - Command word for continuing transfer</p>
19 RXMSK	<p>Receive Data Mask</p> <p>When set, receive data is masked (receive data is not stored in receive FIFO).</p> <p>0b - Normal transfer 1b - Receive data is masked</p>
18 TXMSK	<p>Transmit Data Mask</p> <p>When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In Master mode, the TXMSK bit initiates a new transfer which cannot be aborted by another command word; the TXMSK bit is cleared by hardware at the end of the transfer.</p> <p>0b - Normal transfer 1b - Mask transmit data</p>
17-16 WIDTH	<p>Transfer Width</p> <p>Configures between serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set.</p> <p>00b - 1 bit transfer 01b - 2 bit transfer 10b - 4 bit transfer 11b - Reserved</p>
15-12 —	Reserved
11-0 FRAMESZ	<p>Frame Size</p> <p>Configures the frame size in number of bits equal to (FRAMESZ + 1).</p> <ul style="list-style-type: none"> <li>The minimum frame size is 8 bits</li> <li>The minimum word size is 2 bits; a frame size of 33 bits is not supported.</li> <li>If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</li> <li>If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits.</li> </ul>

## 48.5.1.16 Transmit Data (TDR)

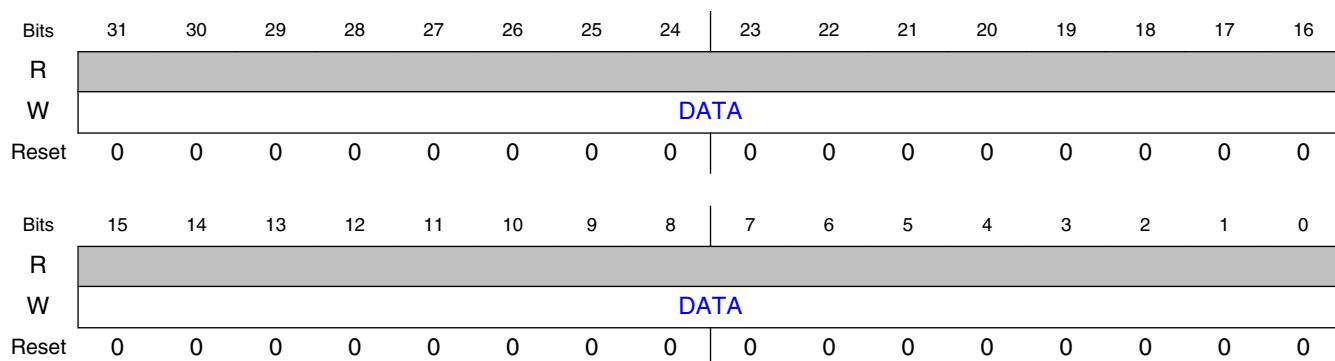

### 48.5.1.16.1 Offset

Register	Offset
TDR	64h

### 48.5.1.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register push the data into the transmit FIFO, in the order that the data was written. The Data Register can be written using 32-bit, 16-bit, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

### 48.5.1.16.3 Diagram

### 48.5.1.16.4 Fields

Field	Function
31-0	Transmit Data
DATA	Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

### 49.2 Overview

The Low Power Universal Asynchronous Receiver/Transmitter (LPUART) module provides asynchronous, serial communication capability with external devices. LPUART supports non-return-to-zero (NRZ) encoding format and IrDA compatible infrared (low-speed) SIR format. The LPUART can continue operating while the processor is in low-power mode if an appropriate peripheral clock is available.

#### 49.2.1 Block diagram

The following figure shows the transmitter portion of the LPUART.

**Figure 49-1. LPUART transmitter block diagram**

The following figure shows the receiver portion of the LPUART.

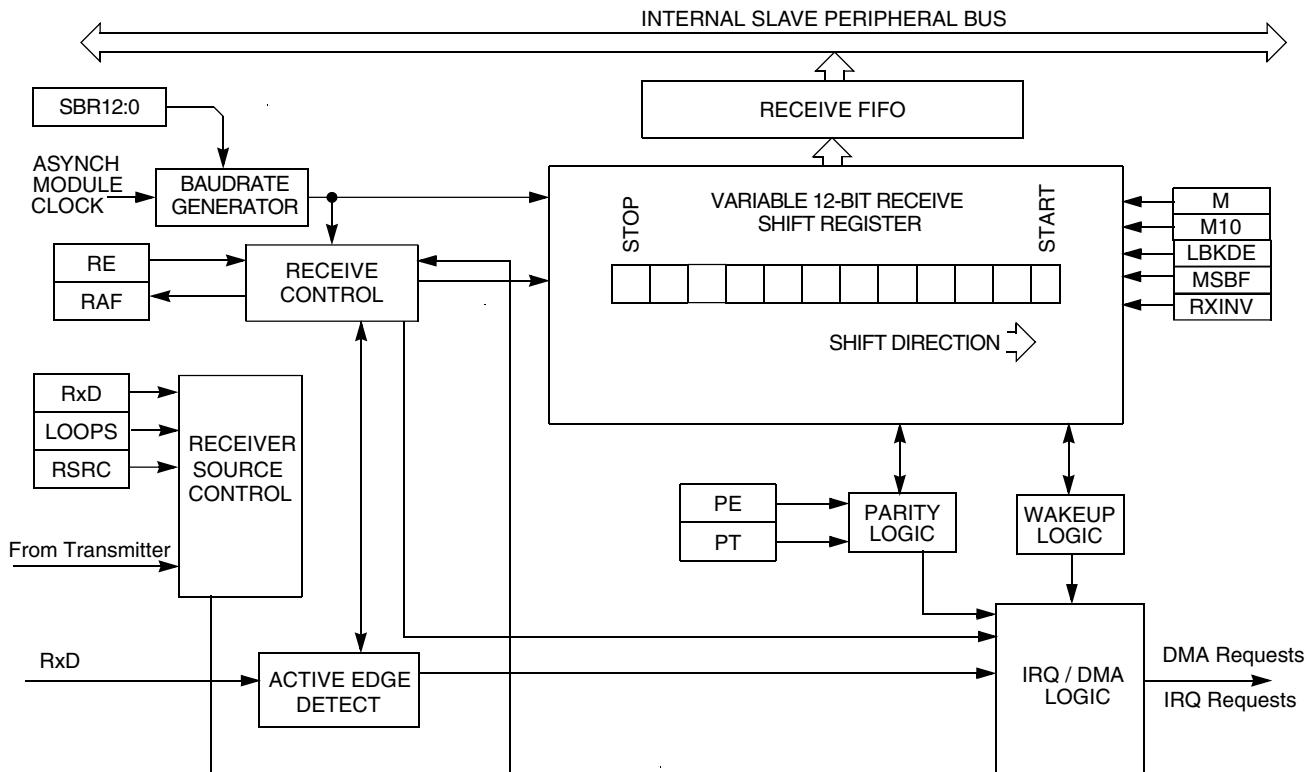

Figure 49-2. LPUART receiver block diagram

## 49.2.2 Features

Following are the features of the LPUART module.

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Asynchronous operation of transmit and receive baud rate with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in low-power modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length

- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit/11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

## 49.3 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

### 49.3.1 Low-power modes

The LPUART remains functional during low power modes, provided the CTRL[DOZEEN] bit is clear and the LPUART functional clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from low power modes.

The LPUART can be configured to be disabled in low power modes, when the CTRL[DOZEEN] bit is set. In this case the transmitter and receiver finish transmitting/receiving the current word.

If the LPUART is disabled in low power modes, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

### NOTE

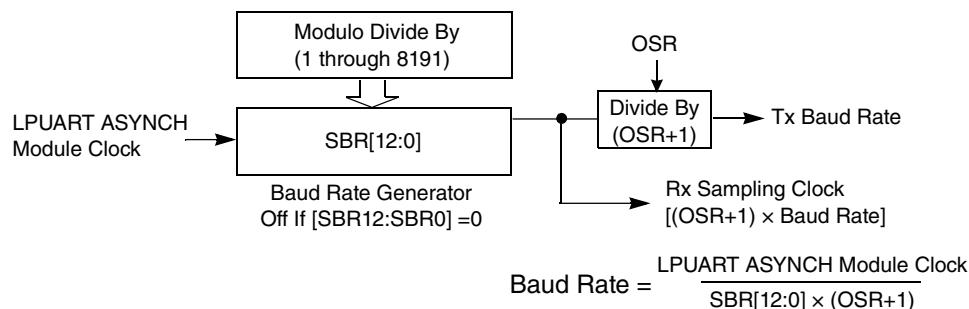

See the chip-specific information to know the specific low-power modes available on your device.

### 49.3.2 Debug mode

The LPUART remains functional in debug mode.

### 49.3.3 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio (OSR). Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

**Figure 49-3. LPUART baud rate generation**

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher oversampling ratio and/or sampling on both edges of the clock slightly improves the LPUART tolerance to baud rate mismatch between the received data and the LPUART configured baud rate. However, the three data samples in each bit will also be closer together which may impact noise sensitivity.

#### **49.3.4 Transmitter functional description**

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted by setting CTRL[TXINV]. CTRL[TXINV] is cleared following reset. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit FIFO. Programs store data into the transmit FIFO by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the transmit shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit FIFO at the DATA register.

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter does not start transmitting another character.

### 49.3.4.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with DATA[FRETSC] set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 0, and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with DATA[FRETSC] and DATA[T9] set, and all other bits cleared. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

**Table 49-2. Break character length**

BRK13	M	M10	M7	SBNS	Break character length
0	0	0	0	0	10 bit times
0	0	0	0	1	11 bit times
0	0	0	1	0	9 bit times
0	0	0	1	1	10 bit times
0	1	0	X	0	11 bit times
0	1	0	X	1	12 bit times

*Table continues on the next page...*

**Table 49-2. Break character length (continued)**

BRK13	M	M10	M7	SBNS	Break character length
0	X	1	X	0	12 bit times
0	X	1	X	1	13 bit times
1	0	0	0	0	13 bit times
1	0	0	0	1	13 bit times
1	0	0	1	0	12 bit times
1	0	0	1	1	12 bit times
1	1	0	X	0	14 bit times
1	1	0	X	1	14 bit times
1	X	1	X	0	15 bit times
1	X	1	X	1	15 bit times

#### 49.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS\_B. If the clear-to-send operation is enabled, the character is transmitted when CTS\_B is asserted. If CTS\_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register will be complete; any characters in the FIFO will wait for the CTS\_B to assert again and TXD remains in the mark state (idle state) until CTS\_B is reasserted. The CTS\_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS\_B.

The transmitter's CTS\_B signal can be enabled even if the same LPUART receiver's RTS\_B signal is disabled.

#### 49.3.4.3 Transceiver driver enable

The transmitter can use RTS\_B as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using RTS\\_B](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmit shift register, RTS\_B asserts one bit time before the start bit is transmitted. RTS\_B remains asserted for the whole time that the transmit shift register has any characters. RTS\_B deasserts one bit time after all characters in the transmit FIFO and shift register are completely sent,

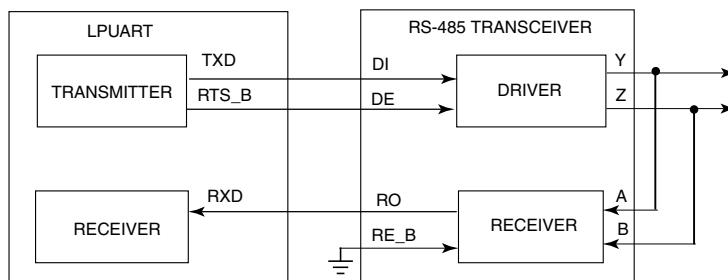

including the last stop bit. In other words, when RTS\_B is used as a transceiver enable, the RTS\_B asserts 1 bit time before the transmitter starts transmitting and negates 1 bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS\_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS\_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS\_B signal is unaffected by its CTS\_B signal. RTS\_B remains asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

#### 49.3.4.4 Transceiver driver enable using RTS\_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS\_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS\_B can be matched to the polarity of the transceiver's driver enable signal.

**Figure 49-4. Transceiver driver enable using RTS\_B**

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS\_B to both DE and RE\_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

#### 49.3.5 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to [Data Modes](#). For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost.

Since the LPUART receiver is separate from the receive FIFO, the receive shift register can be receiving the next word when the receive FIFO is full and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to [Interrupts and status flags](#) for details about flag clearing.

#### **49.3.5.1 Data sampling technique**

The LPUART receiver supports a configurable oversampling rate of between 4 $\times$  and 32 $\times$  of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE]=1), the number of segments in each received bit is effectively doubled (from 1 to OSR $\times$ 2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4 $\times$  to 7 $\times$  and is optional for higher oversampling rates.

The "synchronization" is a feature of the LPUART module to synchronize the internal oversampling counter with detected falling edge on Rx signal, and to adjust the data sampling window. The falling edge detection needs three consecutive '1' prior to '1'->'0' transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter once another falling edge is detected. This is called "resynchronization".

- When LPUART\_BAUD[RESYNCDIS] = 0, this falling edge detection and resynchronization is performed not only for the start bit but also for the rest of character reception after the start bit.
- When LPUART\_BAUD[RESYNCDIS] = 1, the falling edge detection and resynchronization is performed only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

See the following table and figure.

**Table 49-3. LPUART resynchronization**

Resynchronization	LPUART_BAUD[RESYNCDIS]=0	LPUART_BAUD[RESYNCDIS]=1
For the starting bit falling edge	Yes	Yes
For every falling edges after the start bit	Yes	No

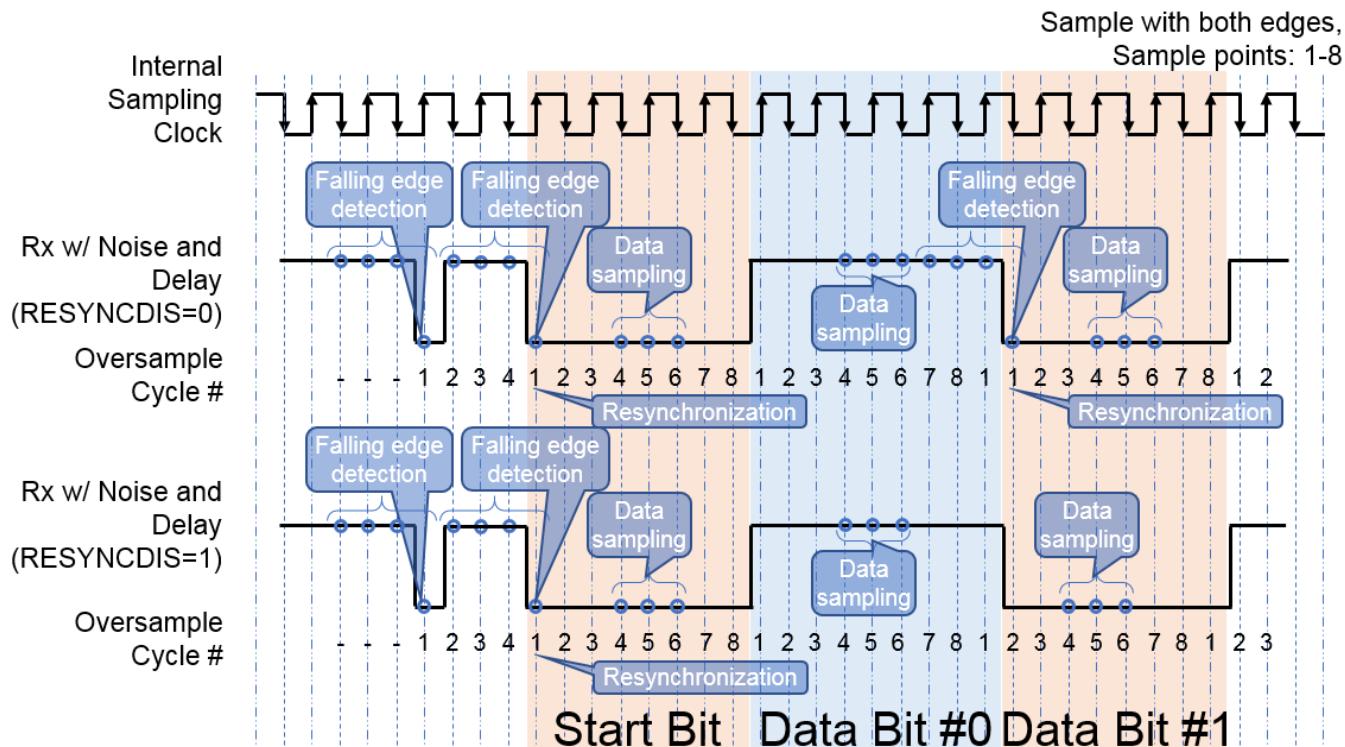

Figure 49-5. LPUART resynchronization

### 49.3.5.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 49-4. Receiver Wakeup Options

RWU	MA1   MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation

Table continues on the next page...

**Table 49-4. Receiver Wakeup Options (continued)**

RWU	MA1   MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set
1	0	00	10	Receiver wakeup on address mark
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match On and Match Off, IDLE flag not set for discarded characters
0	1	10	X1	Match On and Match Off, IDLE flag set for discarded characters

#### 49.3.5.2.1 Idle-line wakeup

When CTRL[WAKE] is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7], and BAUD[M10] control bits select 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line.

- When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle.
- When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

#### 49.3.5.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

#### 49.3.5.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

#### 49.3.5.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs then no transfer is made to the receive FIFO, and all following characters with logic zero in the most significant bit (or

second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

#### 49.3.5.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is transferred only to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive FIFO, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

### 49.3.5.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

#### NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

### 49.3.5.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS\_B.

- RTS\_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using RTS\\_B](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS\_B if the number of characters in the receiver data register is full or a start bit is detected that causes the receiver data register to be full.
- The receiver asserts RTS\_B when the number of characters in the receiver data register is not full and has not detected a start bit that causes the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS\_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS\_B remains deasserted.

### 49.3.6 Additional LPUART functions

The following sections describe additional LPUART functions.

### 49.3.6.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the 9th and 10th bit are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0], but if values in CTRL[T8] or CTRL[T9] do not need to change then it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to the DATA register.

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10-bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the 9th and 10th bit are held in CTRL[R8] and CTRL[R9] but should be read before reading the DATA register. A 16-bit or 32-bit read of the receive FIFO will return all 10-bits in the DATA register.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

### 49.3.6.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position (idle state, generally logic 1). The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit causes any discarded characters to be treated as if they were idle characters.

### 49.3.6.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

### 49.3.6.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

## 49.3.7 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. The LPUART IrDA support is limited to SIR mode which supports data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode (external to LPUART) and transformed to CMOS levels by the IR receive decoder. The narrow pulses are then stretched by the infrared receive decoder to get back

to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

#### 49.3.7.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

#### 49.3.7.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

#### 49.3.7.3 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 49.3.7.4 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

### 49.3.7.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

### 49.3.7.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

## 49.3.8 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit Data Register Empty (STAT[TDRE]) indicates when there is room in the transmit FIFO to write another transmit character to the DATA register. If the Transmit Interrupt Enable (CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to be set, the error flags — noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) — are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] is already set when a new character is ready to be transferred from the receive shifter to the receive FIFO, the overrun (STAT[OR]) flag is set instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

## 49.3.9 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

### 49.3.9.1 Output Triggers

The LPUART generates the following output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when the idle flag would set, for one oversampling clock period.

### 49.3.9.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

## Clocking and Resets

- The CTS function must be enabled. The input trigger can be connected in place of the CTS\_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be a free running clock (carrier signal) generated from a timer or PWM source with a frequency that is greater than the bit clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

## 49.4 Clocking and Resets

**Table 49-5. Clocks**

LPUART Functional clock	The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

**Table 49-6. Resets**

Chip reset	The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.
Software reset	Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].
FIFO reset	The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty.

## 49.5 External signals

Signal	Description	I/O
TXD	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O
RXD	Receive data.	I
CTS_B	Clear to send.	I
RTS_B	Request to send.	O

## 49.6 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map generates a bus error.

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 49.6.1 LPUART register descriptions

#### 49.6.1.1 LPUART memory map

LPUART1 base address: 4018\_4000h [Serial6](#)

LPUART2 base address: 4018\_8000h [Serial3](#)

LPUART3 base address: 4018\_C000h [Serial2 \(or Serial4 on MicroMod\)](#)

LPUART4 base address: 4019\_0000h [Serial4 \(or Serial2 on MicroMod\)](#)

LPUART5 base address: 4019\_4000h [Serial8](#)

LPUART6 base address: 4019\_8000h [Serial1](#)

Field	Function
31 MAEN1	Match Address Mode Enable 1 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA1].
30 MAEN2	Match Address Mode Enable 2 0b - Normal operation. 1b - Enables automatic address matching or data matching mode for MATCH[MA2].
29 M10	10-bit Mode select The M10 bit causes a tenth bit to be part of the serial transmission. This bit should be changed only when the transmitter and receiver are both disabled.

Table continues on the next page...

Field	Function
	0b - Receiver and transmitter use 7-bit to 9-bit data characters. 1b - Receiver and transmitter use 10-bit data characters.
28-24 OSR	Oversampling Ratio  This field configures the oversampling ratio for the receiver. This field should be changed only when the transmitter and receiver are both disabled. 00000b - Writing 0 to this field results in an oversampling ratio of 16 00001b - Reserved 00010b - Reserved 00011b - Oversampling ratio of 4, requires BOTHEDGE to be set. 00100b - Oversampling ratio of 5, requires BOTHEDGE to be set. 00101b - Oversampling ratio of 6, requires BOTHEDGE to be set. 00110b - Oversampling ratio of 7, requires BOTHEDGE to be set. 00111b - Oversampling ratio of 8. 01000b - Oversampling ratio of 9. 01001b - Oversampling ratio of 10. 01010b - Oversampling ratio of 11. 01011b - Oversampling ratio of 12. 01100b - Oversampling ratio of 13. 01101b - Oversampling ratio of 14. 01110b - Oversampling ratio of 15. 01111b - Oversampling ratio of 16. 10000b - Oversampling ratio of 17. 10001b - Oversampling ratio of 18. 10010b - Oversampling ratio of 19. 10011b - Oversampling ratio of 20. 10100b - Oversampling ratio of 21. 10101b - Oversampling ratio of 22. 10110b - Oversampling ratio of 23. 10111b - Oversampling ratio of 24. 11000b - Oversampling ratio of 25. 11001b - Oversampling ratio of 26. 11010b - Oversampling ratio of 27. 11011b - Oversampling ratio of 28. 11100b - Oversampling ratio of 29. 11101b - Oversampling ratio of 30. 11110b - Oversampling ratio of 31. 11111b - Oversampling ratio of 32.
23 TDMAE	Transmitter DMA Enable  TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable  RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
20 —	Reserved
19-18 MATCFG	Match Configuration  Configures the match addressing mode used. This field should be changed only when the transmitter and receiver are both disabled.

*Table continues on the next page...*

## Register definition

Field	Function
	00b - Address Match Wakeup 01b - Idle Match Wakeup 10b - Match On and Match Off 11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTEDGE	<b>Both Edge Sampling</b> Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should be changed only when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock. 1b - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	<b>Resynchronization Disable</b> When set, this field disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should be changed only when the receiver is disabled. 0b - Resynchronization during received data word is supported. 1b - Resynchronization during received data word is disabled.
15 LBKDIIE	<b>LIN Break Detect Interrupt Enable</b> LBKDIIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0b - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1b - Hardware interrupt is requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	<b>RX Input Active Edge Interrupt Enable</b> Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOPS] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0b - Hardware interrupts from STAT[RXEDGIF] are disabled. 1b - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13 SBNS	<b>Stop Bit Number Select</b> SBNS determines whether data characters have one or two stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - One stop bit. 1b - Two stop bits.
12-0 SBR	<b>Baud Rate Modulo Divisor.</b> The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) * SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

### 49.6.1.7.3 Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. Writing a 1 clears the LBKDIF field. 0b - No LIN break character has been detected. 1b - LIN break character has been detected.
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge (falling if RXINV = 0, rising if RXINV=1,) on the RXD pin occurs. To clear RXEDGIF, write a 1 to the RXEDGIF field. 0b - No active edge on the receive pin has occurred. 1b - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1b - MSB (identified as bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10].
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should be changed only when the receiver is disabled. <b>NOTE:</b> Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Receive data not inverted. 1b - Receive data inverted.
27 RWUID	Receive Wake Up Idle Detect

Table continues on the next page...

## Register definition

Field	Function
	<p>For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should be changed only when the receiver is disabled.</p> <p>0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.</p> <p>1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.</p>
26 BRK13	<p>Break Character Generation Length</p> <p>BRK13 selects a longer transmitted break character length. The state of this bit does not affect the detection of a framing error. This bit should be changed only when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.</p> <p>0b - Break character is transmitted with length of 9 to 13 bit times. 1b - Break character is transmitted with length of 12 to 15 bit times.</p>
25 LBKDE	<p>LIN Break Detection Enable</p> <p>LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive FIFO.</p> <p><b>NOTE:</b> The LBKDE bit enables the LIN break detect circuit and disables writing receive data to FIFO. So it essentially ignores all characters except a LIN break.</p> <p>0b - LIN break detect is disabled, normal break character can be detected. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).</p>
24 RAF	<p>Receiver Active Flag</p> <p>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.</p> <p>0b - LPUART receiver idle waiting for a start bit. 1b - LPUART receiver active (RXD input not idle).</p>
23 TDRE	<p>Transmit Data Register Empty Flag</p> <p>When the transmit FIFO is enabled, TDRE is set when the number of datwords in the transmit FIFO is equal to or less than the number indicated by WATER[TXWATER]. To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE is set when the transmit DATA register is empty. To clear TDRE, write to the DATA register.</p> <p>TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character.</p> <p>0b - Transmit FIFO level is greater than watermark. 1b - Transmit FIFO level is equal or less than watermark.</p>
22 TC	<p>Transmission Complete Flag</p> <p>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK].</p> <p>0b - Transmitter active (sending data, a preamble, or a break). 1b - Transmitter idle (transmission activity complete).</p>
21 RDRF	<p>Receive Data Register Full Flag</p>

Table continues on the next page...

Field	Function
	<p>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive FIFO is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register.</p> <p>A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character continues to be received until an overrun condition occurs once the entire character is received.</p> <p>0b - Receive FIFO level is less than watermark. 1b - Receive FIFO level is equal or greater than watermark.</p>
20 IDLE	<p>Idle Line Flag</p> <p>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.</p> <p>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character is stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period.</p> <p>0b - No idle line detected. 1b - Idle line is detected.</p>
19 OR	<p>Receiver Overrun Flag</p> <p>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.</p> <p>While the OR flag is set, no additional data is stored in the receive FIFO even if sufficient room exists. To clear OR, write logic 1 to the OR flag.</p> <p>0b - No overrun. 1b - Receive overrun (new LPUART data lost).</p>
18 NF	<p>Noise Flag</p> <p>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register is received with noise detected within the character. To clear NF, write logic 1 to the NF field.</p> <p>0b - No noise detected. 1b - Noise detected in the received character in the DATA register.</p>
17 FE	<p>Framing Error Flag</p> <p>FE is set whenever the next character to be read from the DATA register is received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field.</p> <p>0b - No framing error detected. This does not guarantee the framing is correct. 1b - Framing error.</p>
16 PF	<p>Parity Error Flag</p> <p>PF is set whenever the next character to be read from the DATA register is received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field.</p>

Table continues on the next page...

## Register definition

Field	Function
	0b - No parity error. 1b - Parity error.
15 MA1F	Match 1 Flag  MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0b - Received data is not equal to MA1 1b - Received data is equal to MA1
14 MA2F	Match 2 Flag  MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0b - Received data is not equal to MA2 1b - Received data is equal to MA2

## 49.6.1.8 LPUART Control Register (CTRL)

### 49.6.1.8.1 Offset

Register	Offset
CTRL	18h

### 49.6.1.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

### 49.6.1.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 49.6.1.8.4 Fields

Field	Function
31 R8T9	Receive Bit 8 / Transmit Bit 9  R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register.  T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written.  <b>NOTE:</b> R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8  R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register  T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written.  <b>NOTE:</b> R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode  When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter finishes receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0b - TXD pin is an input in single-wire mode. 1b - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion  Setting this bit reverses the polarity of the transmitted data output.  <b>NOTE:</b> Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Transmit data not inverted. 1b - Transmit data inverted.
27	Overrun Interrupt Enable

Table continues on the next page...

## Register definition

Field	Function
ORIE	This bit enables the overrun flag (OR) to generate hardware interrupt requests. 0b - OR interrupts disabled; use polling. 1b - Hardware interrupt is requested when OR is set.
26 NEIE	Noise Error Interrupt Enable  This bit enables the noise flag (NF) to generate hardware interrupt requests. 0b - NF interrupts disabled; use polling. 1b - Hardware interrupt is requested when NF is set.
25 FEIE	Framing Error Interrupt Enable  This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt is requested when FE is set.
24 PEIE	Parity Error Interrupt Enable  This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling. 1b - Hardware interrupt is requested when PF is set.
23 TIE	Transmit Interrupt Enable  Enables STAT[TDRE] to generate interrupt requests. 0b - Hardware interrupts from TDRE disabled. 1b - Hardware interrupt is requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for  TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0b - Hardware interrupts from TC disabled. 1b - Hardware interrupt is requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable  Enables STAT[RDRF] to generate interrupt requests. 0b - Hardware interrupts from RDRF disabled. 1b - Hardware interrupt is requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable  ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0b - Hardware interrupts from IDLE disabled; use polling. 1b - Hardware interrupt is requested when IDLE flag is 1.
19 TE	Transmitter Enable  Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit reads as 1 until the transmitter has completed the current character and the TXD pin is tristated.  A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0b - Transmitter disabled. 1b - Transmitter enabled.
18 RE	Receiver Enable  Enables the LPUART receiver. When RE is written to 0, this register bit reads as 1 until the receiver finishes receiving the current character (if any). 0b - Receiver disabled. 1b - Receiver enabled.
17 RWU	Receiver Wakeup Control

Table continues on the next page...

Field	Function
	<p>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set and STAT[RWUID] is clear.</p> <p><b>NOTE:</b> RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.</p> <p>0b - Normal receiver operation. 1b - LPUART receiver in standby waiting for wakeup condition.</p>
16 SBK	<p>Send Break</p> <p>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. If software takes too long to clear SBK (for example, it is not cleared by the end of the 1st break character), then a 2nd break character is sent. This is compared to queuing a break character through the transmit FIFO which guarantees only one is sent.</p> <p>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.</p> <p>0b - Normal transmitter operation. 1b - Queue break character(s) to be sent.</p>
15 MA1IE	<p>Match 1 Interrupt Enable</p> <p>0b - MA1F interrupt disabled 1b - MA1F interrupt enabled</p>
14 MA2IE	<p>Match 2 Interrupt Enable</p> <p>0b - MA2F interrupt disabled 1b - MA2F interrupt enabled</p>
13-12 —	Reserved
11 M7	<p>7-Bit Mode Select</p> <p>This bit should be changed only when the transmitter and receiver are both disabled.</p> <p>0b - Receiver and transmitter use 8-bit to 10-bit data characters. 1b - Receiver and transmitter use 7-bit data characters.</p>
10-8 IDLECFG	<p>Idle Configuration</p> <p>Configures the number of idle characters that must be received before the IDLE flag is set.</p> <p>000b - 1 idle character 001b - 2 idle characters 010b - 4 idle characters 011b - 8 idle characters 100b - 16 idle characters 101b - 32 idle characters 110b - 64 idle characters 111b - 128 idle characters</p>
7 LOOPS	<p>Loop Mode Select</p> <p>When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.</p> <p>0b - Normal operation - RXD and TXD use separate pins.</p>

*Table continues on the next page...*

## Register definition

Field	Function
	1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0b - LPUART is enabled in Doze mode. 1b - LPUART is disabled in Doze mode .
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select 0b - Receiver and transmitter use 8-bit data characters. 1b - Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1: <ul style="list-style-type: none"><li>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character.</li><li>• An idle condition on the receive pin input signal.</li></ul> 0b - Configures RWU for idle-line wakeup. 1b - Configures RWU with address-mark wakeup.
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.  <b>NOTE:</b> In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - Idle character bit count starts after start bit. 1b - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - No hardware parity generation or checking. 1b - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of logic 1 bits in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity. 1b - Odd parity.

## 49.6.1.9 LPUART Data Register (DATA)

### 49.6.1.9.1 Offset

Register	Offset
DATA	1Ch

### 49.6.1.9.2 Function

#### NOTE

This register is two separate registers. Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags. This register can be written using 8-bit, 16-bit or 32-bit writes. An 8-bit write to DATA[7:0] will push { R8T9, R9T8, DATA[7:0] } the transmit FIFO with TSC clear. A 16-bit or 32-bit write will push the data written into the FIFO and does not update the value in R8T9 or R9T8.

### 49.6.1.9.3 Diagram

### 49.6.1.9.4 Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received The current received dataword contained in DATA[R9:R0] is received with noise. 0b - The dataword is received without noise.

Table continues on the next page...

## Register definition

Field	Function
	1b - The data is received with noise.
14 PARITYE	Parity Error The current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - The dataword is received without a parity error. 1b - The dataword is received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0b - The dataword is received without a frame error on read, or transmit a normal character on write. 1b - The dataword is received with a frame error, or transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer contains valid data. 1b - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0b - Receiver was not idle before receiving this character. 1b - Receiver was idle before receiving this character.
10 —	Reserved
9 R9T9	R9T9 Read receive FIFO bit 9 or write transmit FIFO bit 9.
8 R8T8	R8T8 Read receive FIFO bit 8 or write transmit FIFO bit 8.
7 R7T7	R7T7 Read receive FIFO bit 7 or write transmit FIFO bit 7.
6 R6T6	R6T6 Read receive FIFO bit 6 or write transmit FIFO bit 6.
5 R5T5	R5T5 Read receive FIFO bit 5 or write transmit FIFO bit 5.
4 R4T4	R4T4 Read receive FIFO bit 4 or write transmit FIFO bit 4.
3 R3T3	R3T3 Read receive FIFO bit 3 or write transmit FIFO bit 3.
2 R2T2	R2T2 Read receive FIFO bit 2 or write transmit FIFO bit 2.
1 R1T1	R1T1 Read receive FIFO bit 1 or write transmit FIFO bit 1.
0	ROTO

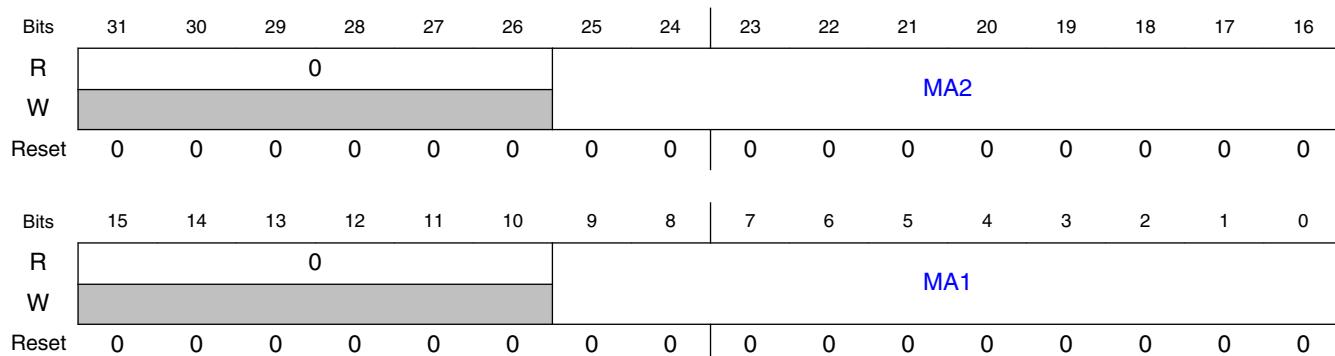

Field	Function
ROTO	Read receive FIFO bit 0 or write transmit FIFO bit 0.

## 49.6.1.10 LPUART Match Address Register (MATCH)

### 49.6.1.10.1 Offset

Register	Offset
MATCH	20h

### 49.6.1.10.2 Diagram

### 49.6.1.10.3 Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2  The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1  The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

## 49.6.1.11 LPUART Modem IrDA Register (MODIR)

### 49.6.1.11.1 Offset

Register	Offset
MODIR	24h

### 49.6.1.11.2 Function

The MODIR register controls options for setting the modem configuration.

### 49.6.1.11.3 Diagram

### 49.6.1.11.4 Fields

Field	Function
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should be changed only when the transmitter and receiver are both disabled. 0b - IR disabled. 1b - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should be changed only when the transmitter and receiver are both disabled.

Table continues on the next page...

Field	Function
	The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00b - 1/OSR. 01b - 2/OSR. 10b - 3/OSR. 11b - 4/OSR.
15-10 —	Reserved
9-8 RTSWATER	Receive RTS Configuration  Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match.  This field should be changed only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source  Configures the source of the CTS input. 0b - CTS input is the CTS_B pin. 1b - CTS input is an internal connection to the receiver address match result.
4 TXCTSC	Transmit CTS Configuration  Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0b - CTS input is sampled at the start of each character. 1b - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable  Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should be changed only when the receiver is disabled.  <b>NOTE:</b> Do not set both RXRTSE and TXRTSE. 0b - The receiver has no effect on RTS. 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity  Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS remains negated in the active low state unless TXRTSE is set. This bit should be changed only when the transmitter is disabled. 0b - Transmitter RTS is active low. 1b - Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable  Controls RTS before and after a transmission. This bit should be changed only when the transmitter is disabled. 0b - The transmitter has no effect on RTS.

*Table continues on the next page...*

## Register definition

Field	Function
	1b - When a character is placed into an empty transmit shift register, RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable  TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0b - CTS has no effect on the transmitter. 1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

## 49.6.1.12 LPUART FIFO Register (FIFO)

### 49.6.1.12.1 Offset

Register	Offset
FIFO	28h

### 49.6.1.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the FIFO is empty.

### 49.6.1.12.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 49.6.1.12.4 Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO/Buffer Empty Asserts when there is no data in the Transmit FIFO/Buffer. This field does not take into account data that is in the transmit shift register. 0b - Transmit buffer is not empty. 1b - Transmit buffer is empty.
22 RXEMPT	Receive FIFO/Buffer Empty Asserts when there is no data in the Receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer is not empty. 1b - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates that more data has been written to the transmit FIFO than it can hold. This field asserts regardless of the value of TXOFE. However, an interrupt is issued to the host only if TXOFE is set. Write 1 to clear this flag. 0b - No transmit FIFO overflow has occurred since the last time the flag was cleared. 1b - At least one transmit FIFO overflow has occurred since the last time the flag was cleared.
16	Receiver FIFO Underflow Flag

Table continues on the next page...

## Register definition

Field	Function
RXUF	Indicates that more data has been read from the receive FIFO than was present. This field asserts regardless of the value of RXUFE. However, an interrupt is issued to the host only if RXUFE is set. Write a logic 1 to clear RXUF. 0b - No receive FIFO underflow has occurred since the last time the flag was cleared. 1b - At least one receive FIFO underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO Flush Writing to this field causes all data that is stored in the transmit FIFO to be flushed. This does not affect data that is in the transmit shift register. 0b - No flush operation occurs. 1b - All data in the transmit FIFO is cleared out.
14 RXFLUSH	Receive FIFO Flush Writing to this field causes all data that is stored in the receive FIFO to be flushed. This does not affect data that is in the receive shift register. 0b - No flush operation occurs. 1b - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0b - TXOF flag does not generate an interrupt to the host. 1b - TXOF flag generates an interrupt to the host.
8 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0b - RXUF flag does not generate an interrupt to the host. 1b - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Transmit FIFO is not enabled. Buffer depth is 1. 1b - Transmit FIFO is enabled. Buffer depth is indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read-only. 000b - Transmit FIFO/Buffer depth = 1 dataword. 001b - Transmit FIFO/Buffer depth = 4 datawords. 010b - Transmit FIFO/Buffer depth = 8 datawords. 011b - Transmit FIFO/Buffer depth = 16 datawords.

Table continues on the next page...

Field	Function
	100b - Transmit FIFO/Buffer depth = 32 datawords. 101b - Transmit FIFO/Buffer depth = 64 datawords. 110b - Transmit FIFO/Buffer depth = 128 datawords. 111b - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	<b>Receive FIFO Enable</b> When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Receive FIFO is not enabled. Buffer depth is 1. 1b - Receive FIFO is enabled. Buffer depth is indicated by RXFIFOSIZE.
2-0 RXFIFOSIZE	<b>Receive FIFO Buffer Depth</b> The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read-only. 000b - Receive FIFO/Buffer depth = 1 dataword. 001b - Receive FIFO/Buffer depth = 4 datawords. 010b - Receive FIFO/Buffer depth = 8 datawords. 011b - Receive FIFO/Buffer depth = 16 datawords. 100b - Receive FIFO/Buffer depth = 32 datawords. 101b - Receive FIFO/Buffer depth = 64 datawords. 110b - Receive FIFO/Buffer depth = 128 datawords. 111b - Receive FIFO/Buffer depth = 256 datawords.

### 49.6.1.13 LPUART Watermark Register (WATER)

#### 49.6.1.13.1 Offset

Register	Offset
WATER	2Ch

#### 49.6.1.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

## Register definition

### 49.6.1.13.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					RXCOUNT			0							
W															RXWATER

### 49.6.1.13.4 Fields

Field	Function
31-27 —	Reserved
26-24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23-18 —	Reserved
17-16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].
15-11 —	Reserved
10-8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
7-2 —	Reserved
1-0	Transmit Watermark

Field	Function
TXWATER	When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

# Chapter 50

## Flexible I/O (FlexIO)

### 50.1 Chip-specific FlexIO information

Table 50-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	—	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Trigger mapping	-	<a href="#">Table 4-8</a>

#### NOTE

In this device, FLEXIO1 and FLEXIO2/3 parameters are not exactly the same. FLEXIO1 has 16 pins, while FLEXIO2/3 has 32 pins.

#### NOTE

FlexIO cannot shift and store on the same cycle. For example, when trying to use FlexIO emulate the SSI slave device, will find it fail to shift and store on the same cycle, and the last falling edge of the clock is not used to latch the last data bit. One workaround is to use other timer count the number bit periods and generate the disable signals. However, it has two limitations: 1) it needs to know the transmitting rate, and set this timer with the same baud rate. 2) it requires the transmitting is asynchronous, does not have any clock stretch; otherwise, it will result in fail. So the slave receiving is not synchronous.

## 50.2 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

### 50.2.1 Block Diagram

The [Figure 50-1](#) gives a high-level overview of the configuration of FlexIO timers and shifters.

The FlexIO uses shifters, timers and external triggers to shift data into or out of the FlexIO. The timing of the data shift is controlled by the timers, as shown in the block diagram. The timers can be configured to use generic timer functions, external triggers, or various other conditions to determine this control.

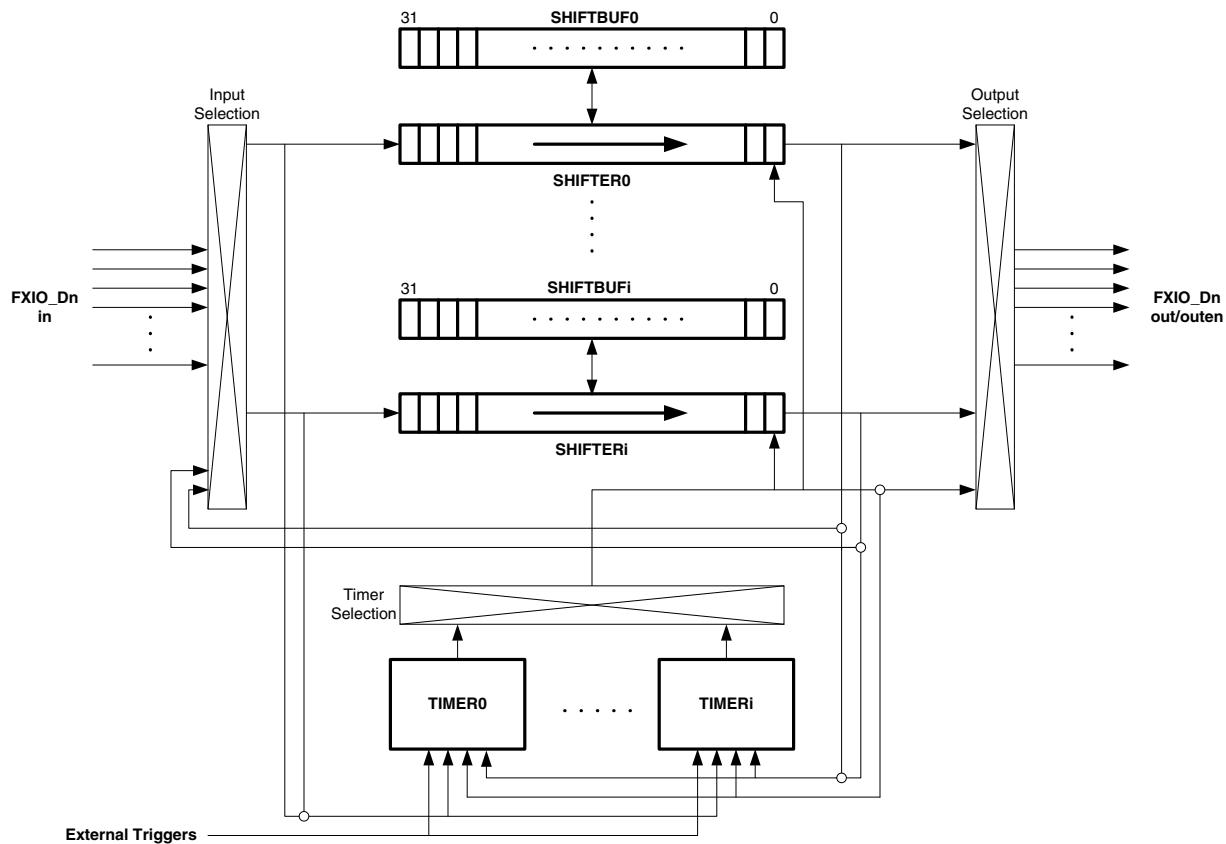

Figure 50-1. FlexIO block diagram

## 50.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive, data match, logic mode, and state modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes

- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

## 50.3 Functional description

### 50.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the **SHIFTCTL[TIMSEL]** register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

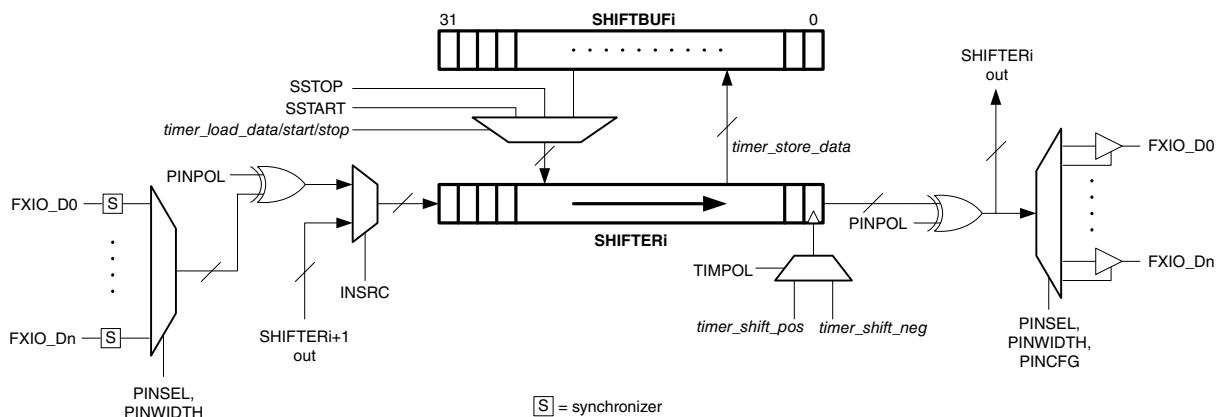

Figure 50-2. Shifter Microarchitecture

### 50.3.1.1 Transmit Mode

When configured for Transmit mode (**SHIFTCTL[SMOD]** =Transmit), the shifter loads data from the **SHIFTBUF** register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after **SHIFTBUF** data by configuring the **SHIFTCFG[SSTART]**, **TIMCFG[TSTART]** or **SHIFTCFG[SSTOP]**, **TIMCFG[TSTOP]** registers in the Shifter and Timer.

#### NOTE

The shifter immediately loads a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set when data has been loaded from the **SHIFTBUF** register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag clears when new data has been written into the **SHIFTBUF** register or a logic 1 is written to this flag. In transmit mode, any write of the **SHIFTBUF** register clears the corresponding Shifter Status Flag. It does not matter what is writing or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/cleared for each mode is documented in the SSF register description.

The Shifter Error Flag (**SHIFTERR[SEF]**) and any enabled interrupts are set when an attempt to load data from an empty **SHIFTBUF** register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

### 50.3.1.2 Receive Mode

When configured for Receive mode (**SHIFTCTL[SMOD]** =Receive), the shifter shifts data in and store data into the **SHIFTBUF** register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the **SHIFTCFG[SSTART]**, **TIMCFG[TSTART]** or **SHIFTCFG[SSTOP]**, **TIMCFG[TSTOP]** registers in the Shifter and Timer.

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set when data has been stored into the **SHIFTBUF** register from the Shifter. The flag clears when the data has been read from the **SHIFTBUF** register or a logic 1 is written to this flag. Any read of the **SHIFTBUF** register clears the corresponding Shifter Status Flag when Shifter is configured in Receive mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (**SHIFTERR[SEF]**) and any enabled interrupts are set when an attempt to store data into a full **SHIFTBUF** register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

### 50.3.1.3 Match Store Mode

When configured for Match Store mode (**SHIFTCTL[SMOD]** =Match Store), the shifter shifts data in, check for a match result and store matched data into the **SHIFTBUF** register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the **SHIFTCFG[SSTART]**, **TIMCFG[TSTART]** or **SHIFTCFG[SSTOP]**, **TIMCFG[TSTOP]** registers in the Shifter and Timer. Up to 16-bits of data can be compared using **SHIFTBUF[31:16]** to configure the data to be matched and **SHIFTBUF[15:0]** to mask the match result.

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set when a match occurs and matched data has been stored into the **SHIFTBUF** register from the Shifter. The flag clears when the matched data has been read from the **SHIFTBUF** register or a logic 1 is written to this flag. Any read of the **SHIFTBUF** register clears the corresponding Shifter Status Flag when Shifter is configured in Match Store mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (**SHIFTERR[SEF]**) and any enabled interrupts are set when an attempt to store matched data into a full **SHIFTBUF** register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

### 50.3.1.4 Match Continuous Mode

When configured for Match Continuous mode (**SHIFTCTL[SMOD]** =Match Continuous), the shifter shifts data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using **SHIFTBUF[31:16]** to configure the data to be matched and **SHIFTBUF[15:0]** to mask the match result.

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between Shifter data and **SHIFTBUF** register. **The flag cannot be cleared by reading the **SHIFTBUF** register.**

The Shifter Error Flag (**SHIFTERR[SEF]**) and any enabled interrupts are set when a match occurs. The flag clears when there is a read from the **SHIFTBUF** register or it is written with logic 1.

### 50.3.1.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a low power mode.

When configured for State mode (**SHIFTCTL[SMOD]** =State), the **SHIFTBUF** register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (**SHIFTSTATE[STATE]**). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

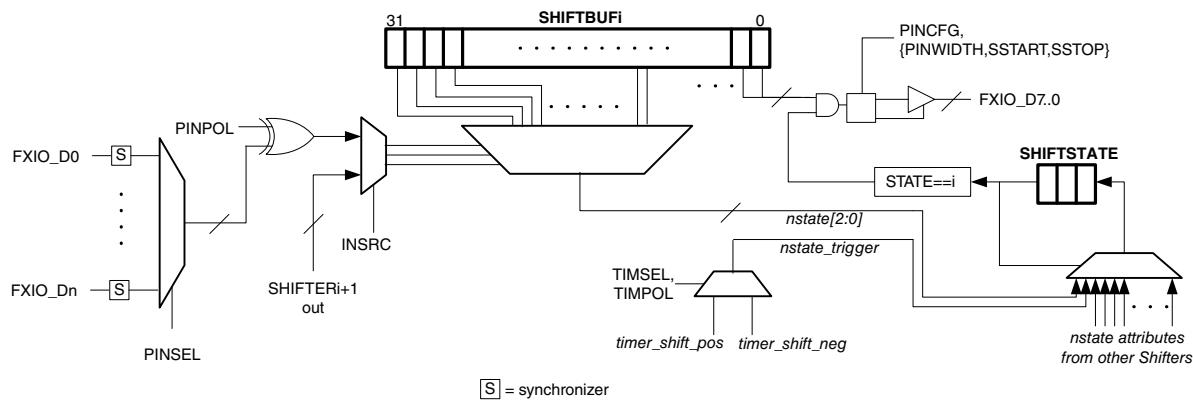

Figure 50-3. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO\_D[7:0] are driven by **SHIFTBUFi[31:24]** using the configuration set by **SHIFTCTLI[PINCFG]**. When set, **SHIFTCFG<sub>i</sub>** {PWIDHT[3:0], SSTOP[1:0], SSTART[1:0]} are respectively used to disable the output drive on pins FXIO\_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by **SHIFTCTLI[PINSEL]** together with **SHIFTBUFi[23:0]**.

**NOTE**

Each state could potentially use a different set of 3 input pins.

The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

**Table 50-2. Next State computation for SHIFTSTATE[STATE]=i**

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by **SHIFTCTLi[TIMSEL]** with polarity controlled by **SHIFTCTLi[TIMPOL]**. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see [Timer section](#) for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

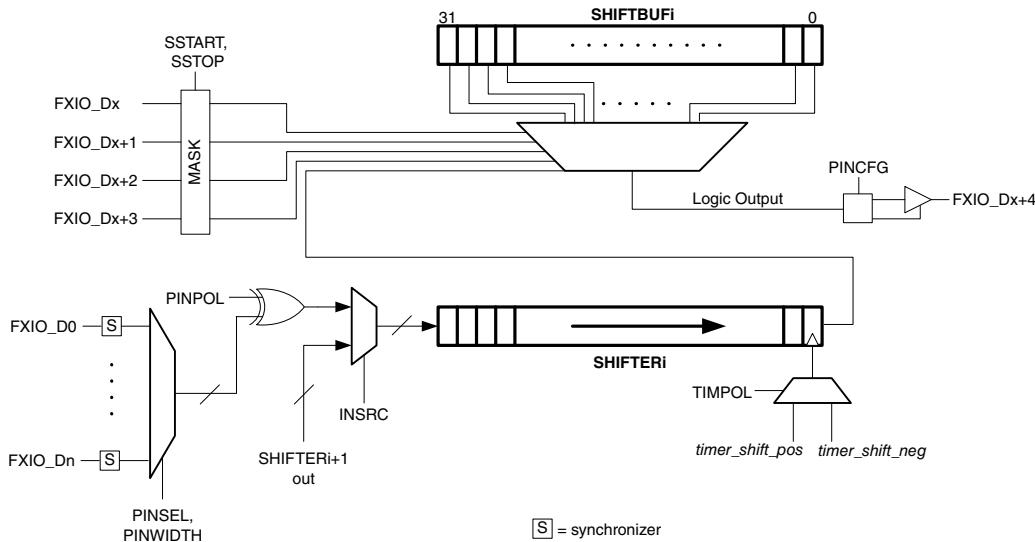

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set whenever the Shifter has been selected by the current state pointer. The flag clears when the current state pointer is updated to a different Shifter.

### 50.3.1.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (**SHIFTCTL[SMOD]** =Logic), the **SHIFTBUFi** register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

The **SHIFTBUFi** configures the lookup table for the 4 pin inputs and the **SHIFTERi** can optionally be used to configure a feedback or delayed pin source as the 5th input to the look up table.

**Figure 50-4. Logic Microarchitecture**

The look-up table is driven using 4 pin inputs (maskable using **SHIFTCFG[SSTOP]** and **SHIFTCFG[SSTART]**) plus 1 input from the internal shifter and can be configured to drive an output pin using the **SHIFTCTL[PINCFG]** field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

**Table 50-3. Logic Look-up table for Shifter 'i'**

SHIFTERi[0]	FXIO_D[x+3] <sup>1</sup>	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	<b>SHIFTBUFi[0]</b>
0	0	0	0	1	<b>SHIFTBUFi[1]</b>
0	0	0	1	0	<b>SHIFTBUFi[2]</b>
0	0	0	1	1	<b>SHIFTBUFi[3]</b>
...	...	...	...	...	...
1	1	1	1	1	<b>SHIFTBUFi[31]</b>

- for Shifter i=0...3, x=i  
for Shifter i=4...7, x=i+4

To minimize output glitches, **SHIFTCFG[SSTOP]** and **SHIFTCFG[SSTART]** can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} mask FXIO\_D[x+3]...FXIO\_D[x] inputs respectively, so that any transitions on these pins does not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

**SHIFTCFG[PWIDTH]** controls the number of delay stages introduced by the internal shifter input (**SHIFTERi[0]**). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter introduces a 32 Shift clock delay before passing its input (selected by **SHIFTCTL[PINSEL]**) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1 Shift clock delay to its input.

The Shifter Status Flag (**SHIFTSTAT[SSF]**) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (**SHIFTERI[SEF]**) and any enabled interrupts are set when the output pin allocated to the logic look-up table has asserted. The flag can be cleared by writing it with logic 1.

### 50.3.2 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (**TIMCFGn**) should be configured before setting the Timer Mode (**TIMOD**).

### 50.3.2.1 Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode only resets the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 50.3.2.2 Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 50.3.2.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: **TIMDEC[1:0]** != 10 or 11) or the number of shift clock edges in the transfer (eg: **TIMDEC[1:0]** = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

#### **50.3.2.4 Timer Enable and Start Bit**

When the **TIMOD** is configured for the desired mode, and the condition configured by timer enable (**TIMENA**) is detected then the following events occur.

- Timer counter loads the current value of the compare Register and start decrementing as configured by **TIMDEC**.
- Timer output may update to its initial state depending on the **TIMOUT** configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by **SSTART**.

If the Timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when **TIMOUT** =1), a shifter that is configured to shift on falling edge and load on the first shift does not load correctly.

#### **50.3.2.5 Timer Decrement and Reset**

The Timer then generates the timer output and timer shift clock depending on the **TIMOD** and **TIMDEC** fields. The shifter clock is either equal to the timer output (when **TIMDEC** != 10 or 11) or equal to the decrement clock (when **TIMDEC** = 10 or 11).

When **TIMDEC** is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

When the Timer is configured to reset as configured in the **TIMRST** field then the Timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by **TIMOUT**. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

### 50.3.2.6 Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events occur.

- Transmit shifters controlled by this timer output their stop bit value (if configured by [SSTOP](#)).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by [SSTOP](#).
- On the first rising edge of the shifter clock after the compare, the timer counter reloads the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable ([TIMDIS](#)) is detected, the following events occur.

- Timer counter reloads the current value of the Compare Register and start decrementing as configured by [TIMDEC](#).
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by [SSTOP](#)).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by [SSTOP](#).

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on

the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

### **50.3.3 Pin operation**

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

#### **50.3.3.1 Parallel Interface**

Shifters can be configured to use multiple FlexIO pins in parallel using the **SHIFTCFG[PWIDTH]** field. **PWIDTH** is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (**SHIFTCFG[INSRC]** =1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter is sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (**SHIFTCFG[INSRC]** =0), with **PWIDTH** and **PINSEL** selecting the pins as follows: FXIO\_D[PINSEL+PWIDTH]:FXIO\_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits are masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO\_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using **SHIFTCTL[PINCFG]**, with **PWIDTH** and **PINSEL** selecting the pins as follows: FXIO\_D[PINSEL+PWIDTH]:FXIO\_D[PINSEL].

Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins are not driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO\_D[12:7] on each Shift clock.

### 50.3.3.2 Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the [FlexIO Application Information Section](#).

### 50.3.4 Low Power Modes

The FlexIO remains functional during low power modes, provided the Doze Enable bit ([CTRL\[DOZEN\]](#)) is clear and the FlexIO functional clock remains enabled.

The exception to this is in LLS mode. In this case, the Doze Enable ([CTRL\[DOZEN\]](#)) bit is ignored and the FlexIO waits for all Timers to complete any pending operation before acknowledging LLS mode entry.

### 50.3.5 Debug Mode

The FlexIO remains functional in debug mode provided the Debug Enable bit ([CTRL\[DBGE\]](#)) is set.

### 50.3.6 Clocks

#### 50.3.6.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least two times faster than the bus clock, the [CTRL\[FASTACC\]](#) bit can be set to support fast register accesses.

#### 50.3.6.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

### 50.3.7 Reset

#### 50.3.7.1 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

#### 50.3.7.2 Software reset

The FlexIO implements a software reset bit in its Control Register. The [CTRL\[SWRST\]](#) resets all logic and registers to their default state, except for the CTRL itself.

### 50.3.8 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

**Table 50-4. FlexIO Interrupts and DMA Requests**

Flag	Description	Interrupt	DMA Request	Low Power Wakeup
<b>SSF</b>	Shifter Status Flag.	Y	Y	Y
<b>SEF</b>	Shifter Error Flag.	Y	N	Y
<b>TSF</b>	Timer Status Flag.	Y	N	Y

## 50.3.9 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

### 50.3.9.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

### 50.3.9.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

## 50.4 Application Information

This section provides examples for a variety of FlexIO module applications.

### 50.4.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the **SSTART** and **SSTOP** fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit

## Application Information

requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to **SHIFTBUFn** (or **SHIFTBUFBIS** for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

**Table 50-5. UART Transmit Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting <b>PINPOL</b> , or can support open drain by setting PINPOL=0x1 and <b>PINCFG</b> =0x1.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_2222	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3.
TIMCTLn	0x01C0_0001	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to <b>SHIFTBUFBBS[7:0]</b> register instead.

An alternative configuration is possible that supports slower baud rates but requires two Timers.

**Table 50-6. UART Transmit Configuration for Slow Baud Rate**

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting <b>PINPOL</b> , or can support open drain by setting PINPOL=0x1 and <b>PINCFG</b> =0x1.

*Table continues on the next page...*

**Table 50-6. UART Transmit Configuration for Slow Baud Rate (continued)**

Register	Value	Comments
TIMCMPn	0x0000_000F	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0x0030_2622	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTLn	0x0740_0003	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(n+1)	0x0000_0001	Configure baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.
TIMCFG(n+1)	0x0000_1200	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=0x3.
TIMCTL(n+1)	0x01C0_0003	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL =0x1 (for Pin 1) and PINPOL =0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

## 50.4.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register returns 0x00.

FlexIO does not support automatic verification of parity bits.

**Table 50-7. UART Receiver Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPln	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2422	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x0000_0081	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS asserts when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit is detected while the RTS is asserted, the received data is simply ignored.

**Table 50-8. UART Receiver with RTS Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPln	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2522	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.

*Table continues on the next page...*

**Table 50-8. UART Receiver with RTS Configuration (continued)**

Register	Value	Comments
TIMCTLn	0x02C0_0081	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0030_6100	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(n+1)	0x0143_0003	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

### 50.4.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

#### NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 50-9. SPI Master (CPHA=0) Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.

SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on negedge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1.

*Table continues on the next page...*

**Table 50-10. SPI Master (CPHA=1) Configuration (continued)**

Register	Value	Comments
		Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0100_2222	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTLn	0x01C3_0201	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock. Set TIMDIS=3 to keep slave select asserted for as long as there is data in the transmit buffer.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0000_1100	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter (never compare) using inverted Pin 3 output (as slave select).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to <a href="#">SHIFTBUFBBS</a> register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from <a href="#">SHIFTBUFBYS</a> , use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from <a href="#">SHIFTBUFBIS</a> register instead.

#### 50.4.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag is set.

#### NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

**Table 50-11. SPI Slave (CPHA=0) Configuration**

## 50.4.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter loads 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

### NOTE

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

**Table 50-13. I2C Master Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTLn	0x0101_0082	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open drain output) on Pin 0.
SHIFTCFG(n+1)	0x0000_0020	Start bit disabled and stop bit enabled (logic 0) for ACK/NACK detection.
SHIFTCTL(n+1)	0x0180_0001	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0x0000_2501	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0102_2222	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	0x01C1_0101	Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0x0000_000F	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_1112	Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.

SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

## 50.4.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

### NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 50-14. I2S Master Configuration**

Register	Value	Comments

TIMCMP(n+1)	0x0000_007F	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0x0000_0100	Enable when Timer 0 is enabled and never disable.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear PINPOL to invert the polarity of the output frame sync
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

### 50.4.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

**NOTE**

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until rising edge of bit clock (when frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

**Table 50-15. I2S Slave Configuration**

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.
SHIFTCTLn	0x0103_0002	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0180_0101	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.
TIMCMPn	0x0000_007F	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.
TIMCFGn	0x0020_2500	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTLn	0x0B40_0203	Configure 16-bit counter using Pin 2 input (bit clock), with Timer 2 output as the trigger.
TIMCMP(n+1)	0x0000_003F	Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_2500	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0x0340_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0x0000_0000	Compare on zero (first edge).
TIMCFG(n+2)	0x0020_6400	Configure enable on inverted pin (frame sync) rising edge and disable on trigger

*Table continues on the next page...*

Register	Value	Comments
		falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	0x04C0_0383	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to <b>SHIFTBUFBIS</b> , use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from <b>SHIFTBUFBIS</b> , use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

## 50.4.8 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

**Table 50-16. Camera Interface Configuration for 8-bit CMOS sensor**

Register	Value	Comments
SHIFTCFGn...n+2 <sup>1</sup>	0x0007_0100	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0x0007_0000	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTLn...n+3	0x0080_0001	Configure receive using Timer 0 on negedge of clock.
TIMCMPn	0x0000_001F	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set

Register	Value	Comments
		TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFGn	0x0120_6600	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge, initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTLn	0x12C0_0803	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF <sub>n</sub> ...n+3	Data to receive	Received data can be read from SHIFTBUF <sub>n</sub> ...n+3, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

1. n=0 or 4

## 50.4.9 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

**Table 50-17. Motorola 68K/Intel 8080 Write Configuration**

Register	Value	Comments
SHIFTCFG0...7	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0x0000_0002	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2200	Configure enable on trigger high and disable on compare. Timer output high on enable.

*Table continues on the next page...*

**Table 50-17. Motorola 68K/Intel 8080 Write Configuration (continued)**

Register	Value	Comments
TIMCTL0	0x01C3_1001 (Motorola 68K, 1-beat) 0x1DC3_1001 (Motorola 68K, 16-beats) 0x01C3_1081 (Intel 8080, 1-beat) 0x1DC3_1081 (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

**Table 50-18. Motorola 68K/Intel 8080 Read Configuration**

Register	Value	Comments
SHIFTCFG0...6	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG7	0x000F_0000	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0x0080_0001	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2220	Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x1DC3_1001 (Motorola 68K, 1 beat) 0x01C3_1001 (Motorola 68K, 16 beats) 0x1DC3_1181 (Intel 8080, 1 beat) 0x01C3_1181 (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K/8080 bus slave begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

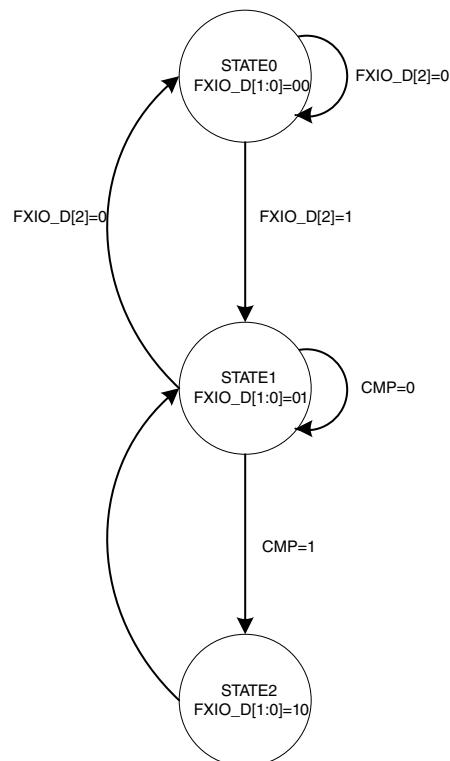

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]

4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

## 50.4.10 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO\_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO\_CLK/131072 on the FXIO\_D[1:0] pins while the comparator output is asserted (This assumes comparator is connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). Throughout this operation, the CPU can be kept in a STOP/VLPS mode by clearing the CTRL[DOZEN] bit and ensuring the FLEXIO\_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

**Figure 50-5. State Diagram**

**Table 50-19. State Machine Configuration**

Register	Value	Comments
SHIFTCFG0..2	0x0000_0003	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF0	0x0020_8208	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0x0000_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state.
SHIFTBUF1	0x0140_8408	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)
SHIFTCTL2	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF2	0x0224_9249	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low
TIMCMP0	0x0000_FFFF	Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_0000	Configure timer always enabled.
TIMCTL0	0x0000_0003	Configure single 16-bit counter.
TIMCFG1	0x0010_7600	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0x0F03_0303	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

### 50.4.11 Keypad Interface

The Keypad Interface can support a 3x4 keypad matrix using 3 timers and 3 shifters, although a larger matrix could be supported using additional shifters. The configuration is designed for 4 columns which are configured as active low open drain pins, and 3 rows which are configured as input pins with pullup resistors enabled.

One shifter is configured in logic mode and is configured to assert its output when any of the row inputs are low, indicating a key is pressed. A timer is used to filter the shifter output to ensure the key is pressed for a minimum amount of time before performing the column scan.

Another shifter is configured for parallel transmit, this shifter is used to scan each column when a key press is detected. Whenever not scanning, the shifter output is configured to assert all active low open drain column outputs to detect any keypress. A dedicated timer is used to control the transmit shifter.

The last shifter is configured for parallel receive, this shifter is used to capture the result of the column scanning for software to decode which key or keys was pressed. This configuration captures the state of both row and column pins for each scan, although the row state could also be deduced by the shift order. A dedicated timer is used to control the receive shifter, it shifts at half the frequency of the transmit shifter.

Once the result of the key scan is available in the receive shifter register, FlexIO continues to monitor the row inputs and can trigger multiple scans from the one key press. To support debouncing, software can decide how many consecutive scans should be considered a single key press.

Since the pins used in logic mode are fixed per shifter, and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond 4 row inputs requires multiple shifters in logic mode and increasing beyond 4 column outputs requires concatenating transmit shifters to create a larger shift register.

**Table 50-20. Keypad Interface Configuration**

Register	Value	Comments
SHIFTCFG0	0x0003_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1), configired for 4-bit shift.
SHIFTCTL0	0x0101_0402	Configure transmit using Timer 1 on rising edge of clock generating open drain output on Pins [7:4] (column outputs).
SHIFTBUF0	0x0804_0201	Static data containing the column scan pattern, each column is scanned one-hot with deadtime inbetween.
SHIFTCFG1	0x0000_0020	In logic mode, mask input 3.
SHIFTCTL1	0x0000_0007	Configure logic mode.
SHIFTBUF1	0x07ff_07ff	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0x0007_0000	Configured for 8-bit shift.
SHIFTCTL3	0x0280_0001	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, pin 0 is don't care).
TIMCMP0	0x0000_00ff	Configures pre-scanning glitch filter to 256 FlexIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.

*Table continues on the next page...*

**Table 50-20. Keypad Interface Configuration (continued)**

Register	Value	Comments
TIMCFG0	0x0103_6600	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0x0540_0003	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0x0000_0f3f	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0x0020_2622	Enable on trigger rising edge, disable on compare, start and stop bits are enabled.
TIMCTL1	0x0340_0001	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0x0000_0801	Configure 4 shifts at half the frequency of Timer 1 trigger.
TIMCFG2	0x0110_2100	Enable on Timer 1 enable, disable on compare, decrement on trigger input with output initially negated and not affected by reset
TIMCTL2	0x0740_0001	Configure dual 8-bit counter using Timer 1 output as the trigger.
SHIFTBUF3	Keypad Scan Result	Keypad scan result can be read from SHIFTBUF3, each byte is the result of one scan with both row and column pin state from the scan (note that pin 0 is not used). Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

21-18 —	Reserved		
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 00b - Timer pin output disabled 01b - Timer pin open drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output		
15-13 —	Reserved		
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL= <i>i</i> selects the FXIO_D <i>i</i> pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. <b>NOTE:</b> This field is not supported in every instance. The following table includes only supported registers.		
	Instance	Field supported in	Field not supported in
	FLEXIO1	TIMCTL0–TIMCTL7[11–8]	TIMCTL0–TIMCTL7[12]
	FLEXIO2	TIMCTL0–TIMCTL7	—
	FLEXIO3	TIMCTL0–TIMCTL7	—
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low		
6-2 —	Reserved		
1-0 TIMOD	Timer Mode In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count.		

Field	Function
	<p>In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal.</p> <p>In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.</p> <ul style="list-style-type: none"> <li>00b - Timer Disabled.</li> <li>01b - Dual 8-bit counters baud mode.</li> <li>10b - Dual 8-bit counters PWM high mode.</li> <li>11b - Single 16-bit counter mode.</li> </ul>

## 50.6.1.21 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

### 50.6.1.21.1 Offset

For  $a = 0$  to 7:

Register	Offset
TIMCFGa	480h + ( $a \times 4h$ )

### 50.6.1.21.2 Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

#### NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

### 50.6.1.21.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 50.6.1.21.4 Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00b - Timer output is logic one when enabled and is not affected by timer reset 01b - Timer output is logic zero when enabled and is not affected by timer reset 10b - Timer output is logic one when enabled and on timer reset 11b - Timer output is logic zero when enabled and on timer reset
23-22 —	Reserved
21-20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 00b - Decrement counter on FlexIO clock, Shift clock equals Timer output. 01b - Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 10b - Decrement counter on Pin input (both edges), Shift clock equals Pin input. 11b - Decrement counter on Trigger input (both edges), Shift clock equals Trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000b - Timer never reset 001b - Reserved 010b - Timer reset on Timer Pin equal to Timer Output 011b - Timer reset on Timer Trigger equal to Timer Output 100b - Timer reset on Timer Pin rising edge 101b - Reserved 110b - Timer reset on Trigger rising edge 111b - Timer reset on Trigger rising or falling edge

Table continues on the next page...

## Memory Map and Registers

Field	Function
15 —	Reserved
14-12 TIMDIS	<p>Timer Disable</p> <p>Configures the condition that causes the Timer to be disabled and stop decrementing.</p> <ul style="list-style-type: none"> <li>000b - Timer never disabled</li> <li>001b - Timer disabled on Timer N-1 disable</li> <li>010b - Timer disabled on Timer compare (upper 8-bits match and decrement)</li> <li>011b - Timer disabled on Timer compare (upper 8-bits match and decrement) and Trigger Low</li> <li>100b - Timer disabled on Pin rising or falling edge</li> <li>101b - Timer disabled on Pin rising or falling edge provided Trigger is high</li> <li>110b - Timer disabled on Trigger falling edge</li> <li>111b - Reserved</li> </ul>
11 —	Reserved
10-8 TIMENA	<p>Timer Enable</p> <p>Configures the condition that causes the Timer to be enabled and start decrementing.</p> <ul style="list-style-type: none"> <li>000b - Timer always enabled</li> <li>001b - Timer enabled on Timer N-1 enable</li> <li>010b - Timer enabled on Trigger high</li> <li>011b - Timer enabled on Trigger high and Pin high</li> <li>100b - Timer enabled on Pin rising edge</li> <li>101b - Timer enabled on Pin rising edge and Trigger high</li> <li>110b - Timer enabled on Trigger rising edge</li> <li>111b - Timer enabled on Trigger rising or falling edge</li> </ul>
7-6 —	Reserved
5-4 TSTOP	<p>Timer Stop Bit</p> <p>The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable.</p> <ul style="list-style-type: none"> <li>00b - Stop bit disabled</li> <li>01b - Stop bit is enabled on timer compare</li> <li>10b - Stop bit is enabled on timer disable</li> <li>11b - Stop bit is enabled on timer compare and timer disable</li> </ul>
3-2 —	Reserved
1 TSTART	<p>Timer Start Bit</p> <p>When start bit is enabled, configured shifters outputs the contents of the start bit when the timer is enabled and the timer counter reloads from the compare register on the first rising edge of the shift clock.</p> <ul style="list-style-type: none"> <li>0b - Start bit disabled</li> <li>1b - Start bit enabled</li> </ul>

# Chapter 51

## Timers Overview

### 51.1 Overview

The following timers are supported in this chip:

- General Purpose Timer (GPT): A 32-bit up-counter with 12-bit pre-scaler
- Periodic Interrupt Timer (PIT): A 32-bit counter timer that features programmable count modulus, clock division features etc.
- Quad Timer (TMR): It provides four timer channels with variety of controls for individual and multi-channel features
- Quadrature Decoder (QDC): It provides interfacing capability to position/speed sensors
- Enhanced FlexPWM: It contains PWM submodules each of which is set up to control a single half bridge power stage
- Watchdog Timer (WDOG1,2): The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors
- Watchdog timer (WDOG3): It is a high reliability independent timer that is available for system use
- External Watchdog Monitor (EWM): It is designed to monitor external circuits, as well as the MCU software flow

#### 51.1.1 General Purpose Timer (GPT)

The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT also features output compare event generation, when the timer matches a preset value, GPT can generate an interrupt for software and a compare event signal on output pins for external hardware.

The GPT has a 12-bit pre-scaler, which provides a programmable clock frequency derived from multiple clock sources.

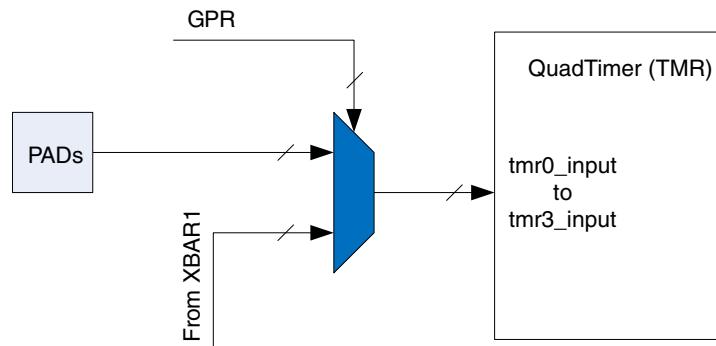

### 51.1.2 Periodic Interrupt Timer (PIT)

The PIT is a basic 32 bit counter timer. It features 32-bit counter timer, programmable count modulus, clock division features, interrupt generation, and ability to chain adjacent timers to achieve longer interval

### 51.1.3 Quad Timer (TMR)

The quad-timer provides four timer channels. Specific features include up/down count, cascading of counters, programmable modulo, count once/repeated, counter preload, compare registers with preload, shared use of input signals, prescaler controls, independent capture/compare, fault input control, programmable input filters, and multi-channel synchronization.

As shown in diagram below, input of QTimer can be sourced from PADs or XBAR1:

### 51.1.4 Enhanced Flex Pulse Width Modulator (eFlexPWM)

This module can generate various switching patterns, including highly sophisticated waveforms. Each module shall be configured with 4 channels supporting A, B, and X PWM output. All channels are configured for standard edge placement and have their capture function enabled.

## 51.1.5 Quadrature Decoder (QDC)

The enhanced Quadrature Decoder module provides interfacing capability to position/speed sensors used in industrial motor control applications. It has five input signals: PHASEA, PHASEB, INDEX, TRIGGER, and HOME. This module is used to decode shaft position, revolution count and speed.

## 51.1.6 Watchdog Timer (WDOG1,2)

The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors.

After WDOG1 and WDOG2 are activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG1 asserts the internal system reset signal, WDOG\_RESET\_B\_DEB to the System Reset Controller (SRC); and WDOG2 asserts interrupt to SNVS to report the security violation condition.

Main features of the WDOG1 and WDOG2 module are:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG\_RESET\_B\_DEB reset signal
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout

## 51.1.7 Watchdog Timer (WDOG3)

The WDOG module is an high reliability independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the CPU.

Main features of the WDOG module are:

- Configurable independent clock source input from bus clock
- Programmable time-out period
- Robust write sequence for counter refresh

- Windowed refresh option
- Optional timeout interrupt to allow post-processing diagnostics
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered
- Robust write sequence for unlocking write-once control/configuration bits

The WDOG3 clock can be sourced from:

- 1MHz RC OSC
- 32KHz clock generated by 32 KHZ XTALOSC which could be automatically switched to 32KHz RC OSC upon XTAL clock loss
- IP Bus Clock

### **51.1.8 External Watchdog Monitor (EWM)**

The External Watchdog Monitor provides a back-up mechanism to the internal WDOG that can reset the system. The EWM differs from the internal WDOG in that it does not reset the system.

The EWM, if allowed to time-out, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode.

# Chapter 52

## General Purpose Timer (GPT)

### 52.1 Chip-specific GPT information

### 52.2 Overview

The General Purpose Timer (GPT) is a 32-bit up-counter with clock source and frequency scaling options to provide a wide range of timing rates for various system applications. External hardware can send the GPT a "capture event" signal on an input pin to load the current timer value into a register for software to read. This capture signal can be configured to trigger the GPT on a rising or/and falling edge. Also, when the timer matches a preset value, the GPT can generate an interrupt for software and a "compare event" signal on output pins for external hardware.

## Overview

**Figure 52-1. GPT Block Diagram**

**Figure 52-2. GPT Counter Clocks Diagram**

### 52.2.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

### 52.3 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip*, except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip. Please see IOMUX Controller for GPT pin mux assignments.

**Table 52-2. Off-Chip Module Signals**

Name	Direction	Function	Reset State	Pull-Up
GPT_CLK	I	Input pin for an external clock that the counter can be operated at.	-	Passive Hysteresis
GPT_CAPTURE1	I	Input pin for a capture event for Input Capture Channel 1.	-	Passive
GPT_CAPTURE2	I	Input pin for a capture event for Input Capture Channel 2.	-	Passive
GPT_COMPARE1	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	0	Passive
GPT_COMPARE2	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	0	Passive
GPT_COMPARE3	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	0	Passive

### 52.3.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose. The external clock input (GPT\_CLK) is treated as asynchronous to the peripheral clock (ipg\_clk). To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock (ipg\_clk). Hysteresis characteristics on this pad will be required because this is a clock input.

### 52.3.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*. A positive / negative edge on these GPT\_CAPTURE $n$  signals can trigger this capture event. These signals are treated as asynchronous to the peripheral clock (ipg\_clk). Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

### 52.3.3 Output Compare Signals

The GPT\_COMPARE $n$  signals indicate that an output compare event has occurred on the corresponding Output Compare Channel  $n$ ; see [Output Compare](#).

## 52.4 Clocks

The clock that is input to the prescaler can be selected from multiple clock sources. The following table describes the clock sources for GPT. See Clock Controller Module (CCM) for clock source connection, configuration and gating information.

**Table 52-3. GPT Clocks**

Clock name	Description
Peripheral Clock (ipg_clk)	This is the internal clock used to access the module registers. If the Peripheral Clock or the External Clock (GPT_CLK) is selected as the Clock Source (CLKSRC=001 or 011), then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock (ipg_clk) can be switched OFF.
Low Reference Clock (ipg_clk_32k)	This low-frequency 32-kHz reference clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode.
High-Frequency Clock (ipg_clk_highfreq)	Provided by the Clock Controller Module (CCM), this high-frequency reference clock is intended to be ON in Normal Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock <i>in Normal Power mode</i> .
Oscillator Clock (ipg_clk_24M)	This 24-MHz oscillator reference clock is intended to be used against frequency changes of the Peripheral Clock (ipg_clk) to provide a more accurate timer clock for system operation. The CCM provides the 24 MHz Oscillator Clock <i>without</i> synchronizing it to the System Bus Clock (ahb_clk) in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24 MHz Oscillator Clock is divided by a dedicated prescaler to make sure the clock frequency less than half of System Bus Clock (ahb_clk).
External Clock (GPT_CLK)	The External Clock comes from <i>outside</i> the device and can be selected to run the GPT counter. The External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock (ipg_clk) for proper GPT operations. Note that in Low Power modes, <i>if</i> the Peripheral Clock (ipg_clk) is not available, then the External Clock <i>cannot be used</i> to run the counter.

The clock input source is configured using the clock source field (CLKSRC, in the GPT\_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT\_CR control register) to 000. **The CLKSRC field value should be changed only after disabling the GPT** (by setting the EN bit in the GPT\_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

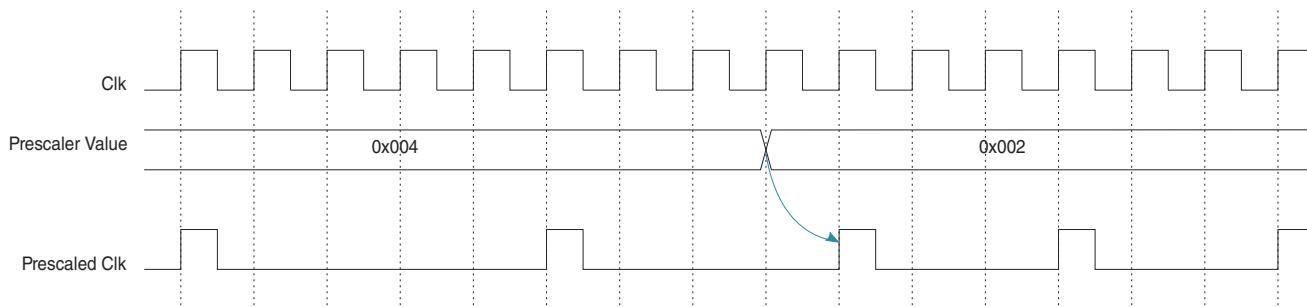

Figure 52-3. Prescaler Value Change Timing Diagram

## 52.5 Functional Description

This section provides a complete functional description of the GPT.

### 52.5.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

#### 52.5.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT\_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

#### 52.5.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

## 52.5.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT\_CNT) that is a 32-bit free-running *up-counter*, which starts counting *after it is enabled by software* (EN=1). The counter's clock source is the output of the prescaler labelled "Prescaler output" in [Figure 52-1](#).

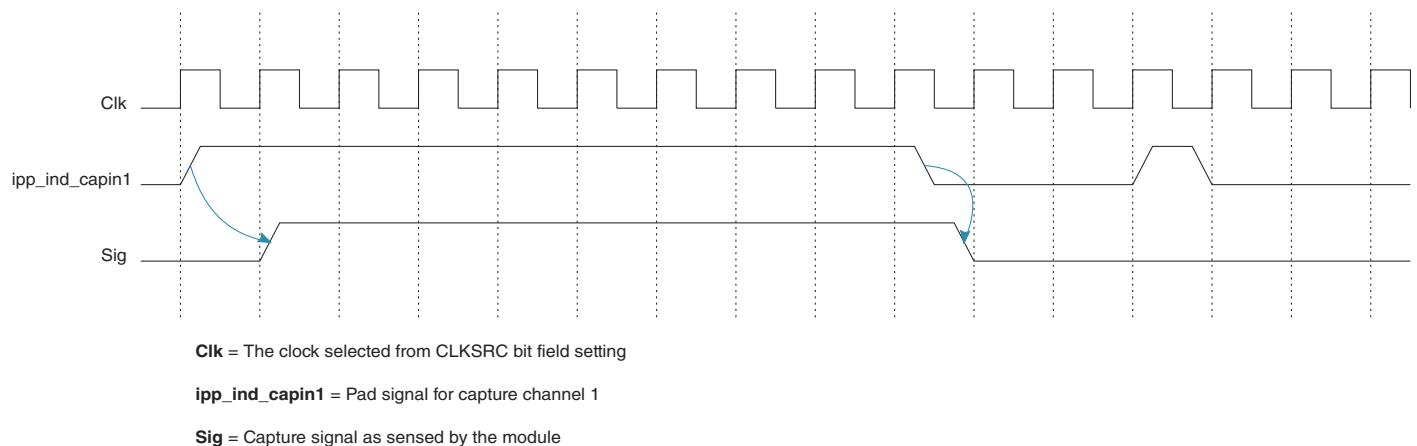

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT\_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT\_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xFFFF\_FFFF.
- The software reset (SWR bit in the GPT\_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

### 52.5.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT\_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and

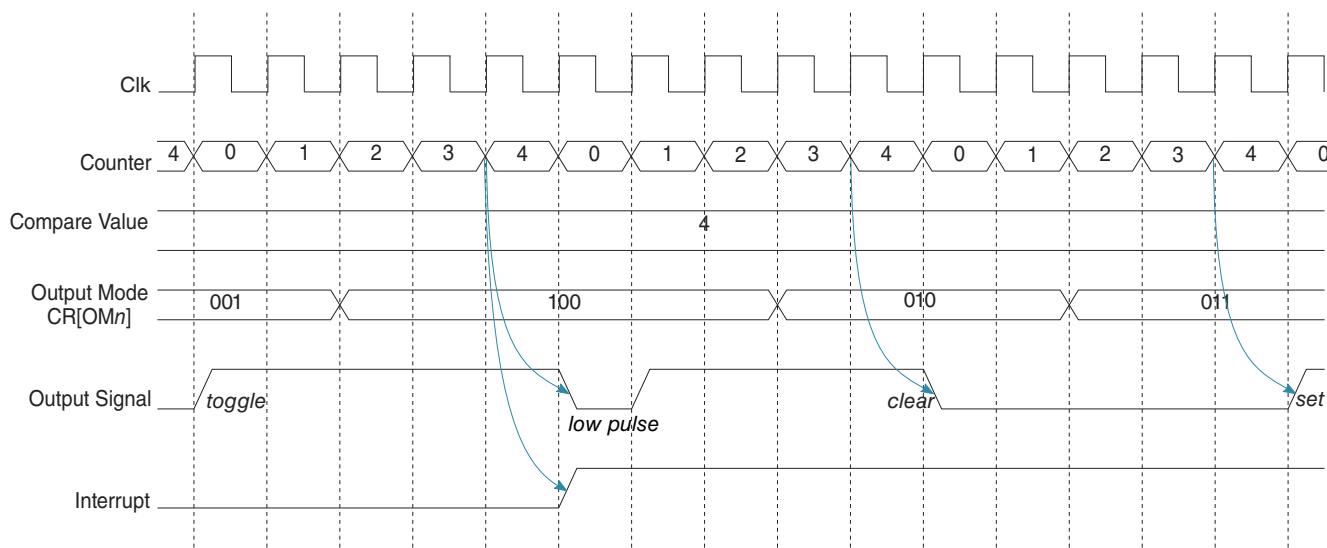

falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

**Figure 52-4. Input Capture Event Timing**

### 52.5.2.2 Output Compare

The three Output Compare Channels *use the same counter* (GPT\_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT\_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin is set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period according to the Output Compare Operating Mode bits in the Control Register (CR[OM $n$ ]).

**Figure 52-5. Output Compare and Interrupt Timing**

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

### 52.5.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT\_IR register; the associated status bit is the ROV bit in the GPT\_SR register.

- Input Capture Interrupt 1, 2

After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT\_IR register); the associated status bits are IF2 and IF1 (in the GPT\_SR register). The capture of the counter value because of a capture event is *not affected*

by a pending capture interrupt. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT\_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT\_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

#### **52.5.2.4 Low Power Mode Behavior**

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock (GPT\_CLK), which can be used *only if* the Peripheral Clock (ipg\_clk) is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT\_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

#### **52.5.2.5 Debug Mode Behavior**

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT\_CR control register), then the GPT timer is halted.

### **52.6 Initialization/ Application Information**

## 52.6.1 Selecting the Clock Source

The Clock Source field in the Control Register (CR[CLKSRC]) selects the clock source. CLKSRC should be changed only after disabling the GPT (CR[EN]=0). To change the clock source, follow this sequence:

1. Disable the GPT: CR[EN]=0
2. Disable GPT interrupts: Clear the Interrupt Register (IR)
3. Configure the Output Mode to unconnected/ disconnected for all channels:  
CR[OM $n$ ]=0
4. Disable the Input Capture Modes: CR[IM $n$ ]=0
5. Change the clock source CR[CLKSRC] to the desired value.
6. Assert a GPT software reset: CR[SWR]=1
7. Clear the flags in the GPT Status Register (SR) by writing 1s to them.
8. Reset the GPT counter to zero: CR[ENMOD]=1
9. Enable the GPT: CR[EN]=1
10. Enable GPT interrupts: For the desired interrupts, write 1s to their enable bits in IR.

## 52.7 Memory map and register definitions

### 52.7.1 GPT register descriptions

The GPT has 10 user-accessible 32-bit registers used to configure, operate and monitor the GPT.

A write access to the GPT Status Registers (Read-only registers ICR1, ICR2, CNT) generates a bus exception.

#### 52.7.1.1 GPT memory map

GPT1 base address: 401E\_C000h

GPT2 base address: 401F\_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	<a href="#">GPT Control Register (CR)</a>	32	RW	0000_0000h
4h	<a href="#">GPT Prescaler Register (PR)</a>	32	RW	0000_0000h

*Table continues on the next page...*

Offset	Register	Width (In bits)	Access	Reset value
8h	GPT Status Register (SR)	32	W1C	0000_0000h
Ch	GPT Interrupt Register (IR)	32	RW	0000_0000h
10h - 18h	GPT Output Compare Register (OCR1 - OCR3)	32	RW	FFFF_FFFFh
1Ch - 20h	GPT Input Capture Register (ICR1 - ICR2)	32	RO	0000_0000h
24h	GPT Counter Register (CNT)	32	RO	0000_0000h

## 52.7.1.2 GPT Control Register (CR)

### 52.7.1.2.1 Offset

Register	Offset
CR	0h

### 52.7.1.2.2 Function

Contains configuration options for GPT operations, such as selecting the clock source for the counter and selecting a channel's output pin response when a compare event occurs. The CR register also includes the control bit (SWR) to trigger a software reset.

#### NOTE

Setting the SWR bit resets **all of the GPT registers** to their default reset values except for the EN, ENMOD, STOPEN, DOZEEN, WAITEN, and DBGEN bits in this register.

For applications where precise timing is critical, be aware that writes to the CR register take effect after one cycle of the module's register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

### 52.7.1.2.3 Diagram

### 52.7.1.2.4 Fields

Field	Function
31-29 FOn	Force Output Compare for Channel n  By setting the FOn bit, software can force the timer Output Compare <i>n</i> pin to respond according to the pin action programmed in the OM <i>n</i> bits (in this register). This bit is self-clearing and always reads as zero.  <b>NOTE:</b> The OF <i>n</i> flag in the Status register (SR) is not set. 0b - No effect 1b - Trigger the programmed response on the pin
28-26: OM3 25-23: OM2 22-20: OM1	Output Compare Operating Mode for Channel n  Selects the response on the output pin when a compare event occurs. 000b - Output disabled. No response on pin. 001b - Toggle output pin 010b - Clear output pin 011b - Set output pin 1xxb - Generate a low pulse that is one input clock cycle wide on the output pin. When OM <i>n</i> is first programmed as 1xx, the output pin is set to one immediately on the next input clock (if it was not one already). "Input clock" here refers to the clock selected by the CLKSRC field of this register.
19-18: IM2 17-16: IM1	Input Capture Operating Mode for Channel n  Selects what transition on the input pin triggers a capture event. 00b - Capture disabled 01b - Capture on rising edge only 10b - Capture on falling edge only 11b - Capture on both edges
15 SWR	Software Reset  Setting SWR resets <b>all of the registers</b> to their default reset values except for the DOZEEN, EN, ENMOD, STOPEN, WAITEN, and DBGEM bits in this register.  The SWR bit remains set while the module is resetting. The SWR bit automatically clears when the reset procedure finishes.  0b - GPT is not in software reset state 1b - GPT is in software reset state
14-11 —	Reserved  Software should write 0s to this reserved field. This field always reads as zero.

Table continues on the next page...

## Memory map and register definitions

Field	Function
10 EN_24M	Enable Oscillator Clock Input  Enables the 24-MHz clock input from an oscillator.  0b - Disable 1b - Enable
9 FRR	Free-Run or Restart Mode  Selects the behavior of the GPT when a compare event in channel 1 occurs.  0b - Restart mode. After a compare event, the counter resets to 0x0000_0000 and resumes counting. 1b - Free-Run mode. After a compare event, the counter continues counting until 0xFFFF_FFFF and then rolls over to 0.
8-6 CLKSRC	Clock Source Select  Selects which clock goes to the prescaler and subsequently runs the GPT counter.  <b>NOTE:</b> The CLKSRC field value should be changed only after disabling the GPT (EN=0). For other programming requirements when changing the clock source, see section <a href="#">Selecting the Clock Source</a> . 000b - No clock 001b - Peripheral Clock (ipg_clk) 010b - High Frequency Reference Clock (ipg_clk_highfreq) 011b - External Clock 100b - Low Frequency Reference Clock (ipg_clk_32k) 101b - Oscillator as Reference Clock (ipg_clk_24M)
5 STOPEN	GPT Stop Mode Enable  Enables GPT operation <i>during Stop mode</i> .  0b - Disable in Stop mode 1b - Enable in Stop mode
4 DOZEEN	GPT Doze Mode Enable  Enables GPT operation <i>during Doze mode</i> .  0b - Disable in Doze mode 1b - Enable in Doze mode
3 WAITEN	GPT Wait Mode Enable  Enables GPT operation <i>during Wait mode</i> .  0b - Disable in Wait mode 1b - Enable in Wait mode
2 DBGGEN	GPT Debug Mode Enable  Enables GPT operation <i>during Debug mode</i> .  0b - Disable in Debug mode 1b - Enable in Debug mode
1 ENMOD	GPT Enable Mode  When the GPT is disabled (EN=0), both the Main Counter and Prescaler Counter <i>freeze their current count values</i> . The ENMOD bit selects the value of the Main Counter and Prescaler Counter when GPT is enabled again (EN=1).  <b>NOTE:</b> If GPT is programmed to be disabled in a low power mode (STOP/WAIT), the Main Counter and Prescaler Counter <i>freeze at their current count values</i> when the GPT enters low power mode. When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value.

Table continues on the next page...

Field	Function
	<p><b>NOTE:</b> A software reset (SWR=1) clears the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits.</p> <p>0b - Restart counting from their frozen values after GPT is enabled (EN=1).</p> <p>1b - Reset counting from 0 after GPT is enabled (EN=1).</p>
0 EN	<p>GPT Enable</p> <p>Enables the GPT module.</p> <p><b>NOTE:</b> Before setting the EN bit, <i>all registers should be properly programmed.</i></p> <p>0b - Disable</p> <p>1b - Enable</p>

### 52.7.1.3 GPT Prescaler Register (PR)

#### 52.7.1.3.1 Offset

Register	Offset
PR	4h

#### 52.7.1.3.2 Function

Contains the *divide value* of the clock that runs the counter.

#### 52.7.1.3.3 Diagram

#### 52.7.1.3.4 Fields

Field	Function
31-16	Reserved

Table continues on the next page...

## Memory map and register definitions

Field	Function
—	Software should write 0s to these reserved bits. These bits always read as zero.
15-12 PRESCALER24 M	Prescaler divide value for the oscillator clock  The 24-MHz oscillator clock is divided by [PRESCALER24M + 1] before selected by the CLKSRC field. If the 24-MHz oscillator clock is not selected, this field takes no effect.  0000b - Divide by 1 0001b - Divide by 2 1111b - Divide by 16
11-0 PRESCALER	Prescaler divide value  The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter.  <b>NOTE:</b> A change in the value of PRESCALER causes the Prescaler counter to reset and a new count period to start immediately. See <a href="#">Clocks</a> for an example timing diagram. 000000000000b - Divide by 1 000000000001b - Divide by 2 111111111111b - Divide by 4096

### 52.7.1.4 GPT Status Register (SR)

#### 52.7.1.4.1 Offset

Register	Offset
SR	8h

#### 52.7.1.4.2 Function

Contains flags to indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The flags are cleared by writing a 1 to them.

#### 52.7.1.4.3 Diagram

Bits	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

#### 52.7.1.4.4 Fields

Field	Function
31-6 —	Reserved Software should write 0s to these reserved bits. These bits always read as zero.
5 ROV	Rollover Flag Indicates that the counter has reached its <i>maximum possible value</i> and <i>rolled over</i> to 0 (from which the counter continues counting). ROV is set only when the counter has reached 0xFFFFFFFF in both Restart and Free-Run modes. 0b - Rollover has not occurred. 1b - Rollover has occurred.
4-3 IFn	Input Capture Flag for Channel n Indicates that a capture event has occurred on Input Capture channel <i>n</i> . 0b - Capture event has not occurred. 1b - Capture event has occurred.
2-0 OFn	Output Compare Flag for Channel n Indicates that a compare event has occurred on Output Compare channel <i>n</i> . 0b - Compare event has not occurred. 1b - Compare event has occurred.

#### 52.7.1.5 GPT Interrupt Register (IR)

##### 52.7.1.5.1 Offset

Register	Offset
IR	Ch

##### 52.7.1.5.2 Function

Contains enable bits that control whether interrupts are generated after rollover, input capture and output compare events.

## Memory map and register definitions

### 52.7.1.5.3 Diagram

### 52.7.1.5.4 Fields

Field	Function
31-6 —	Reserved <ul style="list-style-type: none"> <li>• Writing a value to these reserved bits does not affect GPT operations.</li> <li>• These reserved bits are always read as zero.</li> </ul>
5 ROVIE	Rollover Interrupt Enable Enables the Rollover interrupt. 0b - Disable 1b - Enable
4-3 IFnIE	Input Capture Flag for Channel n Interrupt Enable Enables the Input Capture Flag for Channel <i>n</i> interrupt. 0b - Disable 1b - Enable
2-0 OFnIE	Output Compare Flag for Channel n Interrupt Enable Enables the Output Compare Flag for Channel <i>n</i> interrupt. 0b - Disable 1b - Enable

### 52.7.1.6 GPT Output Compare Register (OCR1 - OCR3)

#### 52.7.1.6.1 Offset

Register	Offset
OCR1	10h
OCR2	14h
OCR3	18h

### 52.7.1.6.2 Function

Holds the value that determines when a compare event is generated on the corresponding Output Compare Channel  $n$ .

#### NOTE

The behavior of OCR1 is different compared with OCR2 and OCR3:

- A write access to OCR1 while in Restart mode (CR[FRR]=0) resets the GPT counter.
- Writes to OCR1 take effect after one cycle of the module's register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

### 52.7.1.6.3 Diagram

Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>
PIT channel to DMA channel correspondence	-	<a href="#">PIT Channel Assignments For Periodic DMA Triggering</a>

There are 4 PIT channels in this device.

### 53.2 Introduction

PIT includes an array of timers that can be used to raise interrupts and trigger DMA channels. Some of the registers listed in [PIT register descriptions](#) are used to configure these timers, and after the expiry of a timer, the respective registers indicate a timeout status, which can be used to raise interrupts and triggers.

#### 53.2.1 Block diagram

The following figure shows the block diagram of PIT module.

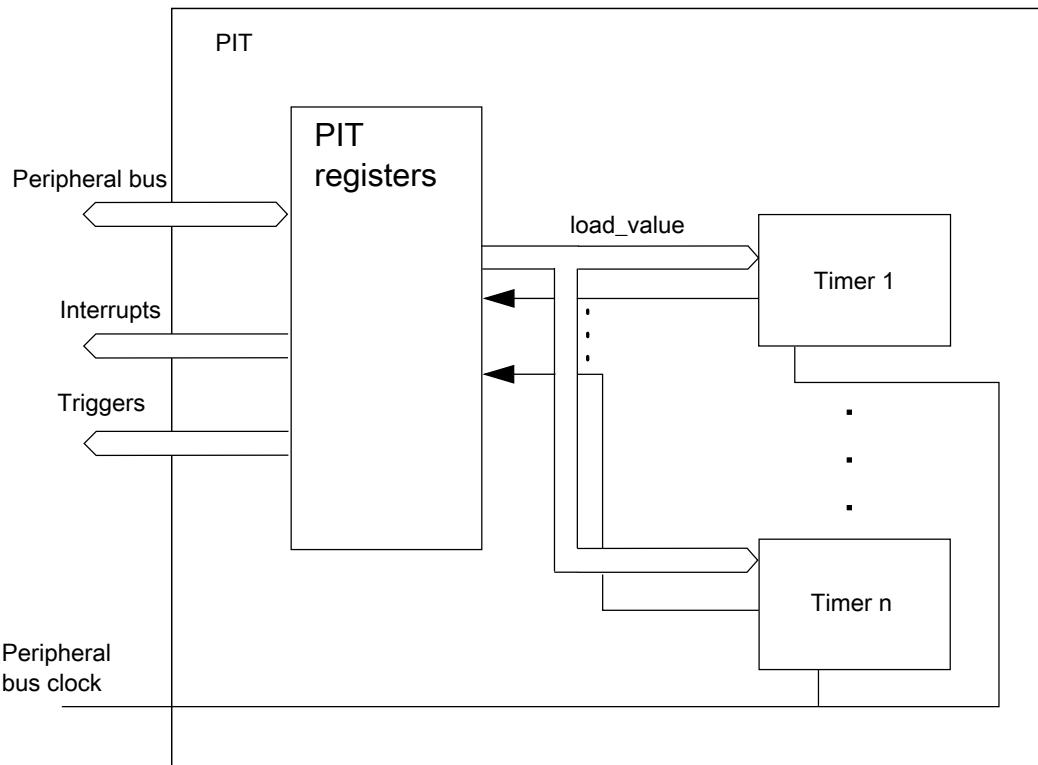

Figure 53-1. Block diagram of PIT

### 53.2.2 Features

The key features of the module are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer
- All the timers use a downcounter

## 53.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode

All functional parts of the PIT are running during normal Run mode.

## 53.4 Functional description

This section provides the functional description of the module.

### 53.4.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line.

#### 53.4.1.1 Timers

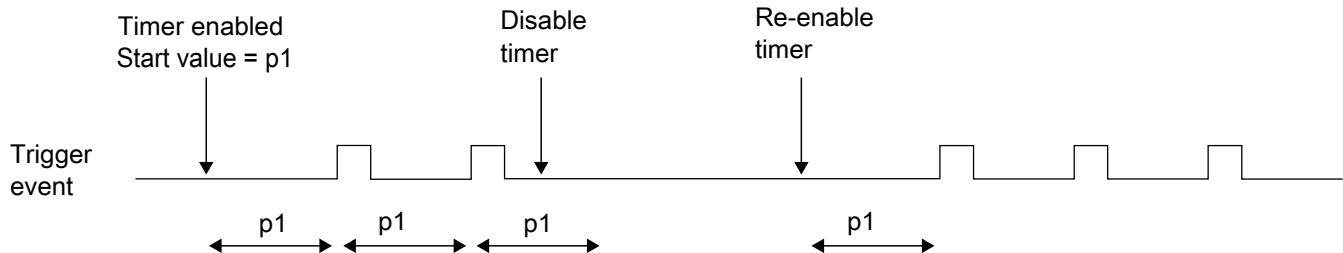

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

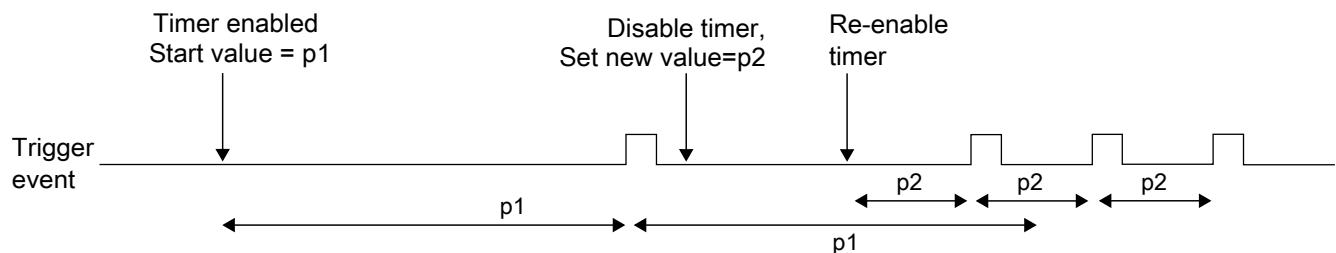

The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

## Functional description

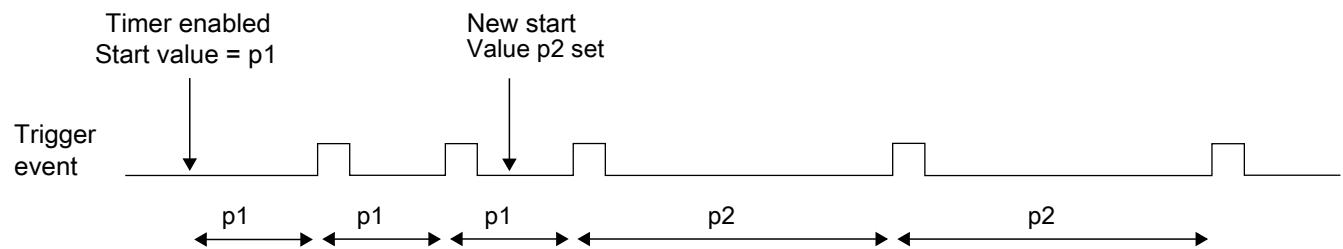

**Figure 53-2. Stopping and starting a timer**

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

**Figure 53-3. Modifying running timer period**

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

**Figure 53-4. Dynamically setting a new load value**

### NOTE

- If MCR[FRZ] is written as 1 and when the timer is nearing 0 (CVALn = 0x0), the debug mode command may not make it to the IP before the timer expires and generates a trigger.

- Debug Mode will be ignored if CVALn =0x0, but the trigger will remain asserted until the mode is removed. The user is recommended to exit Debug mode and then clear the interrupt TFLGn[TIF].
- If the timers are to be freezed for debug, sufficient time must be ensured for the IP to react.

### 53.4.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

### 53.4.2 Interrupts

All the timers support interrupt generation.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

### 53.4.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer. See [Example configuration for chained timers](#) for details.

### 53.4.4 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.

## Functional description

- Timers 1 and 2 are available.
- An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

### 53.4.5 Example configuration for the Lifetime Timer

To configure the Lifetime Timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
```

```

PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0

```

To access the Lifetime Timer, read first LTMR64H and then LTMR64L.

```

current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;

```

## 53.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every  $5.12\text{ ms}/20\text{ ns} = 256,000$  cycles and Timer 3 every  $30\text{ ms}/20\text{ ns} = 1,500,000$  cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) - 1

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. Also, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```

// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

## 53.6 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.

### 53.6.1 PIT memory map

PIT base address: 4008\_4000h

Offset	Register	Width (in bits)	Access	Reset value
0h	PIT Module Control Register (MCR)	32	RW	0000_0002h
E0h	PIT Upper Lifetime Timer Register (LTMR64H)	32	RO	0000_0000h
E4h	PIT Lower Lifetime Timer Register (LTMR64L)	32	RO	0000_0000h
100h	Timer Load Value Register (LDVAL0)	32	RW	0000_0000h
104h	Current Timer Value Register (CVAL0)	32	RO	0000_0000h
108h	Timer Control Register (TCTRL0)	32	RW	0000_0000h
10Ch	Timer Flag Register (TFLG0)	32	W1C	0000_0000h
110h	Timer Load Value Register (LDVAL1)	32	RW	0000_0000h
114h	Current Timer Value Register (CVAL1)	32	RO	0000_0000h
118h	Timer Control Register (TCTRL1)	32	RW	0000_0000h
11Ch	Timer Flag Register (TFLG1)	32	W1C	0000_0000h
120h	Timer Load Value Register (LDVAL2)	32	RW	0000_0000h
124h	Current Timer Value Register (CVAL2)	32	RO	0000_0000h
128h	Timer Control Register (TCTRL2)	32	RW	0000_0000h
12Ch	Timer Flag Register (TFLG2)	32	W1C	0000_0000h
130h	Timer Load Value Register (LDVAL3)	32	RW	0000_0000h
134h	Current Timer Value Register (CVAL3)	32	RO	0000_0000h
138h	Timer Control Register (TCTRL3)	32	RW	0000_0000h
13Ch	Timer Flag Register (TFLG3)	32	W1C	0000_0000h

## 53.6.2 PIT Module Control Register (MCR)

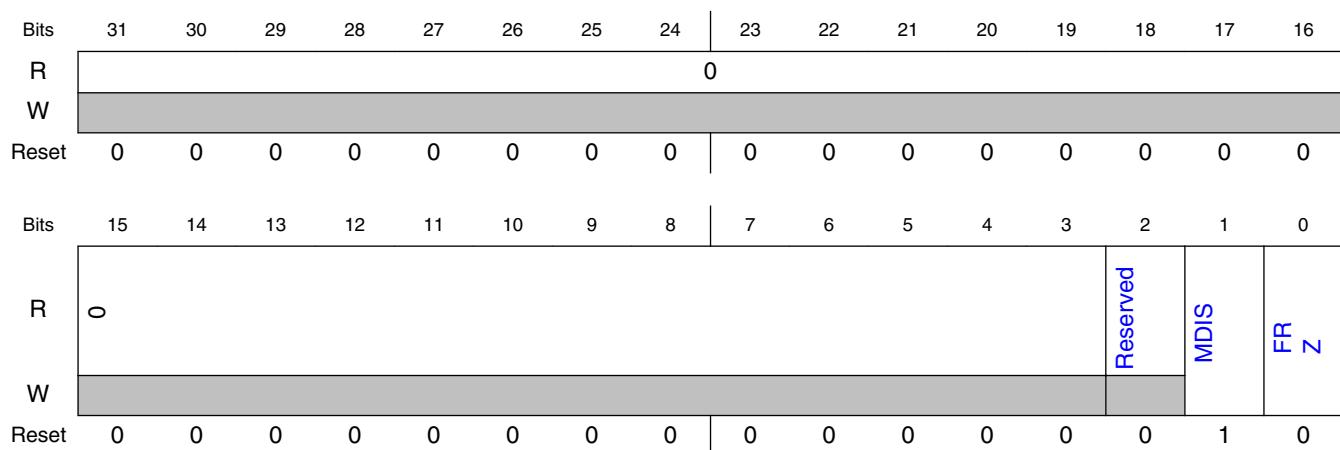

### 53.6.2.1 Offset

Register	Offset
MCR	0h

### 53.6.2.2 Function

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

### 53.6.2.3 Diagram

### 53.6.2.4 Fields

Field	Function
31-3	Reserved
—	
2	Reserved
—	
1	Module Disable for PIT

Table continues on the next page...

## PIT register descriptions

Field	Function
MDIS	Disables the standard timers. You must write 1 to this field before setting up anything. 0b - Clock for standard PIT timers is enabled. 1b - Clock for standard PIT timers is disabled.
0 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0b - Timers continue to run in Debug mode. 1b - Timers are stopped in Debug mode.

## 53.6.3 PIT Upper Lifetime Timer Register (LTMR64H)

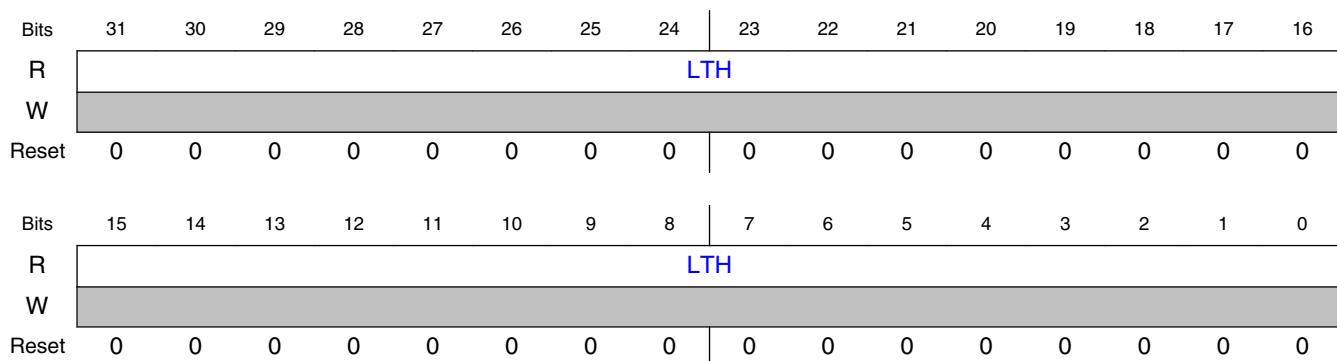

### 53.6.3.1 Offset

Register	Offset
LTMR64H	E0h

### 53.6.3.2 Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

### 53.6.3.3 Diagram

### 53.6.3.4 Fields

Field	Function
31-0	Life Timer value
LTH	Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

## 53.6.4 PIT Lower Lifetime Timer Register (LTMR64L)

### 53.6.4.1 Offset

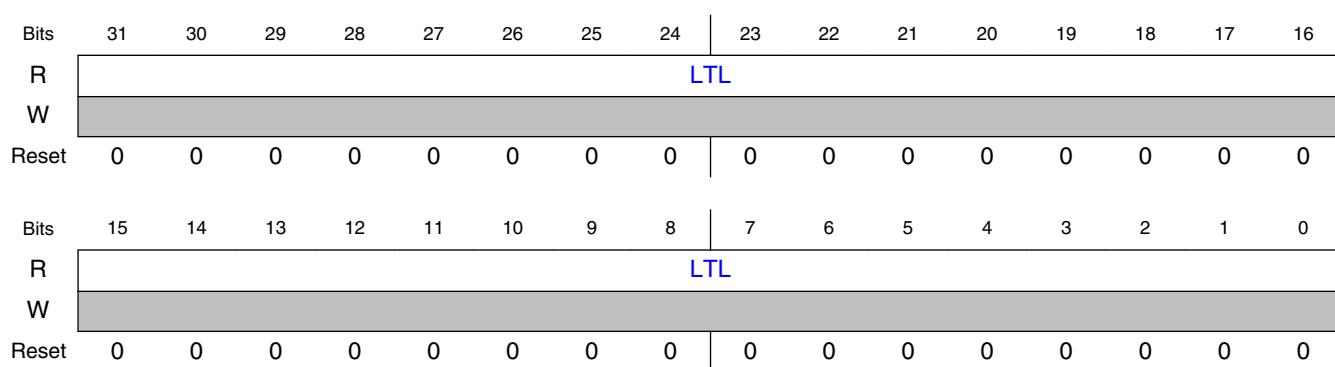

Register	Offset
LTMR64L	E4h

### 53.6.4.2 Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

### 53.6.4.3 Diagram

### 53.6.4.4 Fields

Field	Function
31-0	Life Timer value
LTL	Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

## 53.6.5 Timer Load Value Register (LDVAL0 - LDVAL3)

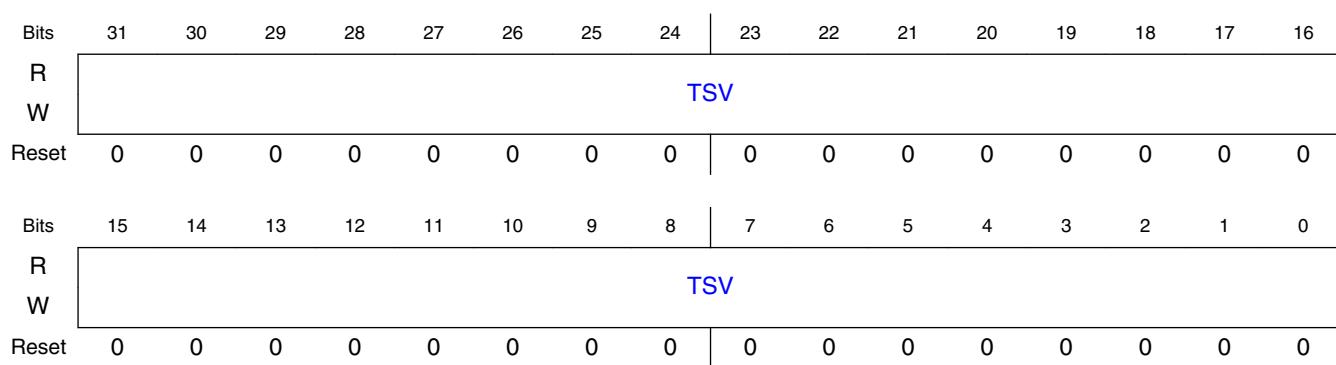

### 53.6.5.1 Offset

Register	Offset
LDVAL0	100h
LDVAL1	110h
LDVAL2	120h
LDVAL3	130h

### 53.6.5.2 Function

These registers select the timeout period for the timer interrupts.

### 53.6.5.3 Diagram

### 53.6.5.4 Fields

Field	Function
31-0	Timer Start Value
TSV	Sets the timer start value. The timer counts down until it reaches 0, then generates an interrupt and loads this register value again. Writing a new value to this register does not restart the timer; instead the value is loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

### 53.6.6 Current Timer Value Register (CVAL0 - CVAL3)

#### 53.6.6.1 Offset

Register	Offset
CVAL0	104h
CVAL1	114h
CVAL2	124h
CVAL3	134h

#### 53.6.6.2 Function

These registers indicate the current timer position.

#### 53.6.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 53.6.6.4 Fields

Field	Function
31-0	Current Timer Value
TVL	Represents the current timer value, if the timer is enabled.  NOTE: <ul style="list-style-type: none"> <li>• If the timer is disabled, do not use this field because its value is unreliable.</li> <li>• The timer uses a downcounter. The timer values are frozen in the Debug mode if MCR[FRZ] is set.</li> </ul>

## 53.6.7 Timer Control Register (TCTRL0 - TCTRL3)

### 53.6.7.1 Offset

Register	Offset
TCTRL0	108h
TCTRL1	118h
TCTRL2	128h
TCTRL3	138h

### 53.6.7.2 Function

These registers contain the control bits for each timer.

### 53.6.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R									0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R									0					CHN	TIE	TEN

### 53.6.7.4 Fields

Field	Function
31-3 —	Reserved
2 CHN	Chain Mode  When activated, timer n-1 needs to expire before timer n (n is > 0) can decrement by 1.  Timer 0 cannot be chained.  0b - Timer is not chained. 1b - Timer is chained to a previous timer. For example, for channel 2, if this field is set, Timer 2 is chained to Timer 1.
1 TIE	Timer Interrupt Enable  When an interrupt is pending, or if TFLGn[TIF] is set, enabling the interrupt causes an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first.  0b - Interrupt requests from Timer n are disabled. 1b - Interrupt is requested whenever TIF is set.
0 TEN	Timer Enable  Enables or disables the timer. 0b - Timer n is disabled. 1b - Timer n is enabled.

### 53.6.8 Timer Flag Register (TFLG0 - TFLG3)

#### 53.6.8.1 Offset

Register	Offset
TFLG0	10Ch
TFLG1	11Ch
TFLG2	12Ch
TFLG3	13Ch

#### 53.6.8.2 Function

These registers hold the PIT interrupt flags.

### 53.6.8.3 Diagram

Bits	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

### 54.2 Overview

Each timer module (TMR) contains four identical counter/timer groups. Each 16-bit counter/timer group contains a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status and control registers, and one control register. All of the registers except the prescaler are read/writable.

#### NOTE

This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The load register provides the initialization value to the counter when the counter's terminal value has been reached.

The hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters.

The capture register enables an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG (TMR Output signal) can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The prescaler provides different time bases useful for clocking the counter/timer.

The counter provides the ability to count internal or external events.

Within a timer module (set of four timer/counters), the four inputs are shared by the four counters, but the four outputs are dedicated to each counter.

### 54.2.1 Block Diagram

Each of the timer/counter groups within the quad-timer are shown in this figure.

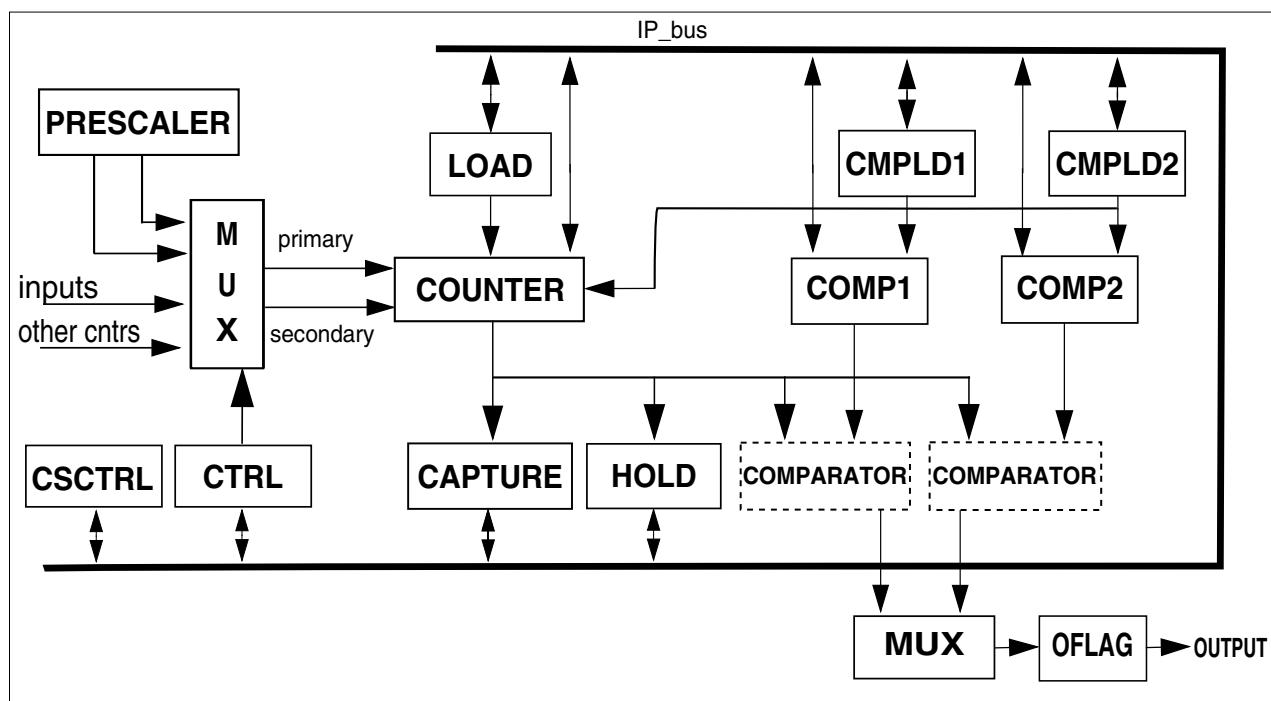

Figure 54-1. Quad Timer Block Diagram

## 54.2.2 Features

The TMR module design includes these distinctive features:

- Four 16-bit counters/timers
- Count up/down
- Counters are cascadable
- Programmable count modulo
- Max count rate equals BUS\_CLOCK\_ROOT/2 for external clocks
- Max count rate equals BUS\_CLOCK\_ROOT for internal clocks
- Count once or repeatedly
- Counters are preloadable
- Compare registers are preloadable (available with compare load feature)
- Counters can share available input pins
- Separate prescaler for each counter
- Each counter has capture and compare capability
- Programmable operation during debug mode
- Inputs may act as fault inputs
- Programmable input filter
- Counting start can be synchronized across counters

## 54.3 Modes of Operation

The TMR module design operates in only a single mode of operation: Functional Mode. The various counting modes are detailed in the Functional Description.

## 54.4 Functional Description

## 54.4.1 General

The counter/timer has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
  - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the four counter/timers within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs are selectable.

The primary output of each timer/counter is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is selectable.

Any counter/timer can be assigned as a master. A master's compare signal can be broadcast to the other counter/timers within the module. The other counters can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a master's counter/timer compare event occurs.

## 54.4.2 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability. The COMP1 register is used when the counter is *counting up*, and the COMP2 register is used when the counter is *counting down*. Alternating compare mode is the only exception.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If CTRL[OUTMODE] is set to 100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time.

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: Count=CMPx, *not* Count > COMP1 or Count < COMP2.

The use of the CMPLD1 and CMPLD2 registers to compare values will help to minimize this problem.

## 54.4.3 Usage of Compare Load Registers

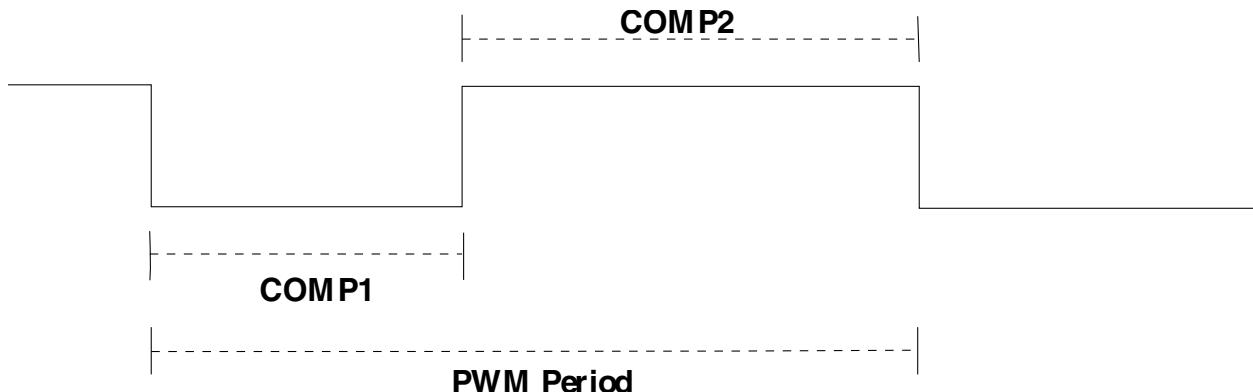

The CMPLD1, CMPLD2, and CSCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. In the past, a compare register could be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there was the possibility that the counter may have already counted past the

new compare value by the time the compare register was updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are now updated in hardware in the same way the counter register is re-initialized to the value stored in the load register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See the following figure.

**Figure 54-2. Variable PWM Waveform**

Should we desire to update the duty cycle or period of the above waveform, we would need to update the COMP1 and COMP2 values using the compare load feature.

#### 54.4.4 Usage of the Capture Register

The capture register stores a copy of the counter's value when an input edge (positive, negative, or both) is detected. After a capture event occurs, no further updating of the capture register will occur until the SCTRL[IEF] (input edge flag) is cleared by writing a zero to the SCTRL[IEF].

## 54.4.5 Functional Modes

The selected external count signals are sampled at the TMR's base clock rate and then run through a transition detector. The maximum count rate is one-half of the TMR's base clock rate. Internal clock sources can be used to clock the counters at the TMR's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CTRL[CM] field is cleared when the count terminates.

### 54.4.5.1 Stop Mode

If CTRL[CM] is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

### 54.4.5.2 Count Mode

If CTRL[CM] is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the negative edge of the selected external input signal is counted.

#### Example: 54.4.5.2.1 Count Pulses from External Source

```
//      This example uses TMR1 to count pulse (actually counts rising edges of the pulse)
//      from an external source (QT3).
//
void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0, PCS=3, SCS=0, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */
    setReg(TMR1_CTRL, 0x0600);           /* Set up mode */
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=0, IEF=0, IEFIE=0, IPS=0, INPUT=0,
       Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */
    setReg(TMR1_SCTRL, 0x00);
    setReg(TMR1_CNTR, 0x00);            /* Reset counter register */
    setReg(TMR1_LOAD, 0x00);            /* Reset load register */
    setRegBitGroup(TMR1_CTRL, CM, 0x01); /* Run counter */
}
```

#### Example: 54.4.5.2.2 Generate Periodic Interrupt By Counting Internal Clocks

```
//      This example generates an interrupt every 100ms,
//      assuming the chip is operating at 60 MHz.
//
```

## Functional Description

```
// It does this by using the IP_bus_clk divided by 128 as the counter clock source.  
// The counter then counts to 46874 where it matches the COMP1 value.  
// At that time an interrupt is generated, the counter is reloaded and  
// the next COMP1 value is loaded from CMPLD1.  
//  
void TimerInt_Init(void)  
{  
    /* TMR0_CTRL: CM=0,PCS=0,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */  
    setReg(TMR0_CTRL,0x20);           /* Stop all functions of the timer */  
    /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,  
     * Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */  
    setReg(TMR0_SCTRL,0x00);  
    setReg(TMR0_LOAD,0x00);           /* Reset load register */  
    setReg(TMR0_COMP1,46874);         /* Set up compare 1 register */  
    setReg(TMR0_CMPLD1,46874);        /* Also set the compare preload register */  
    /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,TCF2EN=0,TCF1EN=1,  
     * TCF2=0,TCF1=0,CL2=0,CL1=1 */  
    setReg(TMR0_CSCTRL,0x41);          /* Enable compare 1 interrupt and */  
                                      /* compare 1 preload */  
    setRegBitGroup(TMR0_CTRL,PCS,0xF); /* Primary Count Source to IP_bus_clk / 128 */  
    setReg(TMR0_CNTR,0x00);           /* Reset counter register */  
    setRegBitGroup(TMR0_CTRL,CM,0x01); /* Run counter */  
}
```

### 54.4.5.3 Edge-Count Mode

If CTRL[CM] is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment, such as a simple encoder wheel.

#### Example: 54.4.5.3.1 Count Both Edges of External Source Signal

```
// This example uses TMR1 to count pulse (actually counts both edges of the pulse)  
// from an external source (QT3).  
//  
void Pulse_Init(void)  
{  
    /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */  
    setReg(TMR1_CTRL,0x0600);          /* Set up mode */  
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,  
     * Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */  
    setReg(TMR1_SCTRL,0x00);  
    setReg(TMR1_CNTR,0x00);           /* Reset counter register */  
    setReg(TMR1_LOAD,0x00);           /* Reset load register */  
    setRegBitGroup(TMR1_CTRL,CM,0x02); /* Run counter */  
}
```

### 54.4.5.4 Gated-Count Mode

If CTRL[CM] is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the counter will count while the selected secondary input is low.

### Example: 54.4.5.4.1 Capture Duration of External Pulse

```

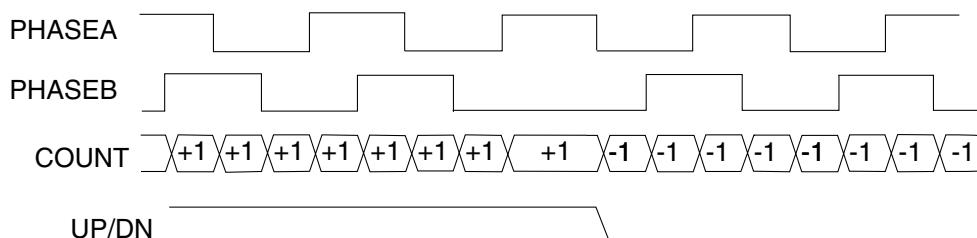

// This example uses TMR1 to determine the duration of an external pulse.
//
// The IP_bus clock is used as the primary counter. If the duration of the
// external pulse is longer than 0.001 seconds one of the other IP_bus clock
// dividers can be used. If the pulse duration is longer than 0.128 seconds
// an external clock source will have to be used as the primary clock source.
//
void Pulse1_Init(void)
{
    /* TMR1_CTRL: CM=0, PCS=8, SCS=1, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */
    setReg(TMR1_CTRL, 0x1080);           /* Set up mode */
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=0, IEF=0, IEFIE=0, IPS=0, INPUT=0,
       Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */
    setReg(TMR1_SCTRL, 0x00);
    setReg(TMR1_CNTR, 0x00);             /* Reset counter register */
    setReg(TMR1_LOAD, 0x00);             /* Reset load register */
    setRegBitGroup(TMR1_CTRL, CM, 0x03); /* Run counter */
}

```

### 54.4.5.5 Quadrature-Count Mode

If CTRL[CM] is set to '100', the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information.

This figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

**Figure 54-3. Quadrature Incremental Position Encoder**

### Example: 54.4.5.5.1 Quadrature Count Mode Example

```

// This example uses TMR0 for counting states of a quadrature position encoder.
//
// Timer input 0 is used as the primary count source (PHASEA).
// Timer input 1 is used as the secondary count source (PHASEB).
//
void Pulse_Init(void)
{
    /* TMRO_CTRL: CM=0, PCS=0, SCS=1, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */

```

## Functional Description

```
setReg(TMRC0_CTRL, 0x80);           /* Set up mode */
/* TMRC0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
   Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
setReg(TMRC0_SCTRL, 0x00);
setReg(TMRC0_CTR, 0x00);            /* Reset counter register */
setReg(TMRC0_LOAD, 0x00);          /* Reset load register */
setReg(TMRC0_COMP1, 0xFFFF);        /* Set up compare 1 register */
setReg(TMRC0_COMP2, 0x00);          /* Set up compare 2 register */
/* TMRC0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
setReg(TMRC0_CSCTRL, 0x00);
setRegBitGroup(TMRC0_CTRL, CM, 0x04); /* Run counter */
}
```

### 54.4.5.6 Quadrature-Count Mode with Index Input

As an extension to the quadrature count mode discussed in the previous paragraph, some rotary shafts have a HOME or INDEX indicator. This would be a third input to the timer that is used to reset the timer's counter.

In this example, channel 0 is used to decode the quadrature inputs, but it doesn't actually count. Because its upper and lower limits are both set to 0, its output is cascaded count up and count down signals each time the quadrature inputs indicate a change in count.

Channel 1 works in cascaded count mode receiving its counting instructions from channel 0. When an input capture event occurs, channel 1 is programmed to reset its counter value. The channel 1 counter contains the position value for the shaft.

#### Example: 54.4.5.6.1 Quadrature Count Mode with Index Input Example

```
// This example uses TMRC0and TMRC1 for counting states of a quadrature position encoder.
//
// Timer input 0 is used as the primary count source (PHASEA).
// Timer input 1 is used as the secondary count source (PHASEB).
// Timer input 2 is used as the index input source (INDEX).
//
void Pulse_Init(void)
{
    /* TMRC0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMRC0_CTRL, 0xA0);           /* Set up mode */
    /* TMRC0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
       Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMRC0_SCTRL, 0x00);
    setReg(TMRC0_CTR, 0x00);            /* Reset counter register */
    setReg(TMRC0_LOAD, 0x00);          /* Reset load register */
    setReg(TMRC0_COMP1, 0x00);          /* Set up compare 1 register */
    setReg(TMRC0_COMP2, 0x00);          /* Set up compare 2 register */
    /* TMRC0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
       TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
    setReg(TMRC0_CSCTRL, 0x00);
    /* TMRC1_CTRL: CM=7,PCS=100,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMRC1_CTRL, 0xEA00);         /* Set up capture edge */
    /* TMRC1_SCTRL: Capture_Mode=10 */
    setReg(TMRC1_SCTRL, 0x0080);
    /* TMRC1_CCTRL: ROC=1 */
    setReg(TMRC1_CTRL, 0x0800);          /* Set up reload on capture */
    setRegBitGroup(TMRC0_CTRL, CM, 0x04); /* Run counter */
}
```

### 54.4.5.7 Signed-Count Mode

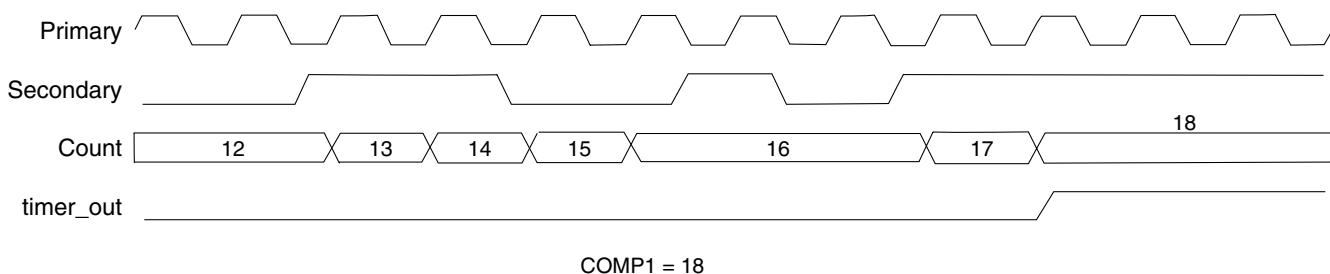

If CTRL[CM] is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

#### Example: 54.4.5.7.1 Signed Count Mode Example

```
// This example uses TMR0 for signed mode counting.
//
// Timer input 2 is used as the primary count source.
// Timer input 1 is used to determine the count direction.
//
void Pulse_Init(void)
{
    /* TMR0_CTRL: CM=0, PCS=2, SCS=1, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */
    setReg(TMR0_CTRL, 0x0480);           /* Set up mode */
    /* TMR0_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=1, IEF=0, IEFIE=0, IPS=0, INPUT=0,
       Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */
    setReg(TMR0_SCTRL, 0x1000);
    setReg(TMR0_CNTR, 0x000);           /* Reset counter register */
    setReg(TMR0_LOAD, 0x000);           /* Reset load register */
    setRegBitGroup(TMR0_CTRL, CM, 0x05); /* Run counter */
}
```

### 54.4.5.8 Triggered-Count Mode 1

If CSCTRL[TCI] is clear and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count is reached, counting will stop and SCTRL[TCF] (timer compare flag) will be set. Subsequent secondary input transitions will continue to restart and stop the counting until a compare event occurs.

**Figure 54-4. Triggered Count Mode 1 (CTRL[LENGTH]=0)**

#### Example: 54.4.5.8.1 Triggered Count Mode 1 Example

## Functional Description

```
// This example uses TMR1 for triggered mode counting.  
//  
// Timer input 3 is used as the primary count source.  
// Timer input 2 is used for the trigger input.  
//  
void Pulse_Init(void)  
{  
    /* TMR1_CTRL: CM=0, PCS=3, SCS=2, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */  
    setReg(TMR1_CTRL, 0x0700);           /* Set up mode */  
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=1, IEF=0, IEFIE=0, IPS=0, INPUT=0,  
     * Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */  
    setReg(TMR1_SCTRL, 0x1000);  
    setReg(TMR1_CNTR, 0x00);             /* Reset counter register */  
    setReg(TMR1_LOAD, 0x00);             /* Reset load register */  
    setReg(TMR1_COMP1, 0x0012);          /* Set up compare 1 register */  
    /* TMR1_CSCTRL: DBG_EN=0, FAULT=0, ALT_LOAD=0, ROC=0, TCI=0, UP=0, OFLAG=0,  
     * TCF2EN=0, TCF1EN=0, TCF2=0, TCF1=0, CL2=0, CL1=0 */  
    setReg(TMR1_CSCTRL, 0x00);  
    setRegBitGroup(TMR1_CTRL, CM, 0x06); /* Run counter */  
}
```

### 54.4.5.9 Triggered-Count Mode 2

If CSCTRL[TCI] is set and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count was reached, the counter will reload and continue counting. When CSCTRL[TCI] is set, the OFLAG output mode, CTRL[OUTMODE], should probably be set to '101' (cleared on init, set on compare) to ensure the output will be in a known state after the second input transition and subsequent reload takes place.

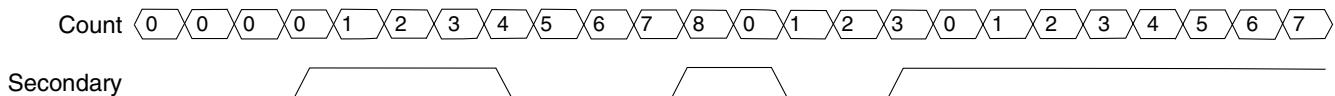

Figure 54-5. Triggered Count Mode 2 (CTRL[LENGTH]=0)

### Example: 54.4.5.9.1 Triggered Count Mode 2 Example

```
// This example uses TMR1 for triggered mode counting.  
//  
// Timer input 3 is used as the primary count source.  
// Timer input 2 is used for the trigger input.  
//  
void Pulse_Init(void)  
{  
    /* TMR1_CTRL: CM=0, PCS=3, SCS=2, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=0 */  
    setReg(TMR1_CTRL, 0x0700);           /* Set up mode */  
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=1, IEF=0, IEFIE=0, IPS=0, INPUT=0,  
     * Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */  
    setReg(TMR1_SCTRL, 0x1000);  
  
    setReg(TMR1_CNTR, 0x00);             /* Reset counter register */
```

```

setReg(TMR1_LOAD, 0x00);           /* Reset load register */
setReg(TMR1_COMP1, 0x0012);        /* Set up compare 1 register */
/* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
setReg(TMR1_CSCTRL, 0x00);
setRegBitGroup(TMR1_CTRL, CM, 0x06); /* Run counter */
}

```

#### 54.4.5.10 One-Shot Mode

If CTRL[CM] is set to '110', and the counter is set to reinitialize at a compare event (CTRL[LENGTH]=1), and CTRL[OUTMODE] is set to '101' (cleared on init, set on compare), the counter works in a one-shot mode. An external event causes the counter to count, and when the terminal count is reached, the output is asserted. This delayed output can be used to provide timing delays.

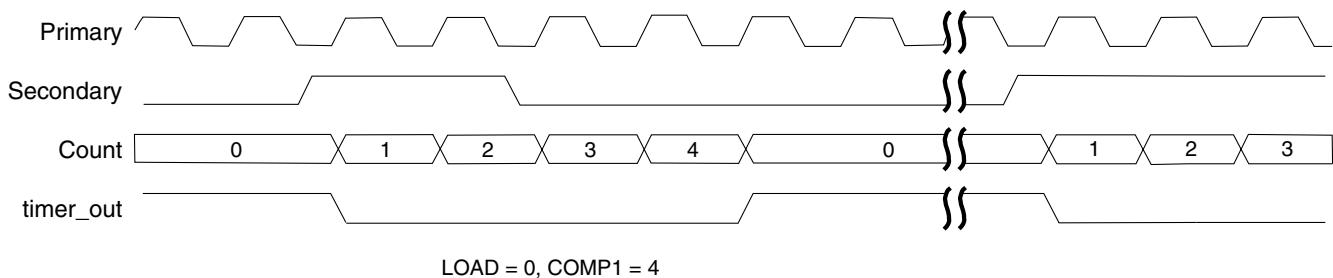

Figure 54-6. One-Shot Mode (CTRL[LENGTH]=1)

#### Example: 54.4.5.10.1 One-Shot Mode Example

```

// This example uses TMR1 for one-shot mode counting.
//
// Timer input 3 is used as the primary count source.
// Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=5 */
    setReg(TMR1_CTRL, 0x0725);           /* Set up mode */
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,INPUT=0,
       Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR1_SCTRL, 0x1000);
    setReg(TMR1_CNTR, 0x00);             /* Reset counter register */
    setReg(TMR1_LOAD, 0x00);             /* Reset load register */
    setReg(TMR1_COMP1, 0x0004);          /* Set up compare 1 register */
    /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
       TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
    setReg(TMR1_CSCTRL, 0x00);
    setRegBitGroup(TMR1_CTRL, CM, 0x06); /* Run counter */
}

```

### 54.4.5.11 Cascade-Count Mode

If CTRL[CM] is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This cascade or daisy-chained mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high-speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to four counters may be cascaded to create a 64-bit wide synchronous counter. Check the data sheet to see if there are any frequency limits for cascaded counting mode.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective hold registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the hold registers of the other counters in the chain. The cascaded counter mode is synchronous.

#### Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a ripple mode, where higher order counters will transition a clock later than a purely synchronous design.

#### Example: 54.4.5.11.1 Generate Periodic Interrupt Cascading Two Counters

```
// This example generates an interrupt every 30 seconds,
// assuming the chip is operating at 60 MHz.
//
// To do this, counter 2 is used to count 60,000 IP_bus clocks, which means it
// will compare and reload every 0.001 seconds.
// Counter 3 is cascaded and used to count the 0.001 second ticks and
// generate the desired interrupt interval.
//
void TimerInt_Init(void)
{
    // Set counter 2 to count IP_bus clocks
    /* TMR2_CTRL: CM=0,PCS=8,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR2_CTRL,0x1020);           /* Stop all functions of the timer */
    // Set counter 3 as cascaded and to count counter 2 outputs
    /* TMR3_CTRL: CM=7,PCS=6,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR3_CTRL,0xEC20);           /* Set up cascade counter mode */
    /* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
     *             Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR3_SCTRL,0x00);
    /* TMR2_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
     *             Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR2_SCTRL,0x00);
}
```

```

setReg(TMR3_CNTR,0x00);           /* Reset counter register */
setReg(TMR2_CNTR,0x00);           /* Reset load register */
setReg(TMR3_LOAD,0x00);
setReg(TMR2_LOAD,0x00);
setReg(TMR3_COMP1, 30000-1);      /* milliseconds in 30 seconds */
setReg(TMR3_CMPLD1,30000-1);
setReg(TMR2_COMP1, 60000-1);      /* Set to cycle every milisecond */
setReg(TMR2_CMPLD1,60000-1);
/* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=1 */
setReg(TMR3_CSCTRL,0x41);         /* Enable compare 1 interrupt and */
                                  /* compare 1 preload */
/* TMR2_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=1 */
setReg(TMR2_CSCTRL,0x01);         /* Enable Compare 1 preload */
setRegBitGroup(TMR2_CTRL,CM,0x01); /* Run counter */
}

```

#### 54.4.5.12 Pulse-Output Mode

If CTRL[CM]=001, and CTRL[OUTMODE] is set to 111' (gated clock output), and CTRL[ONCE] is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

##### Note

This does not work if CTRL[PCS] is set to 1000 (IP\_bus/1).

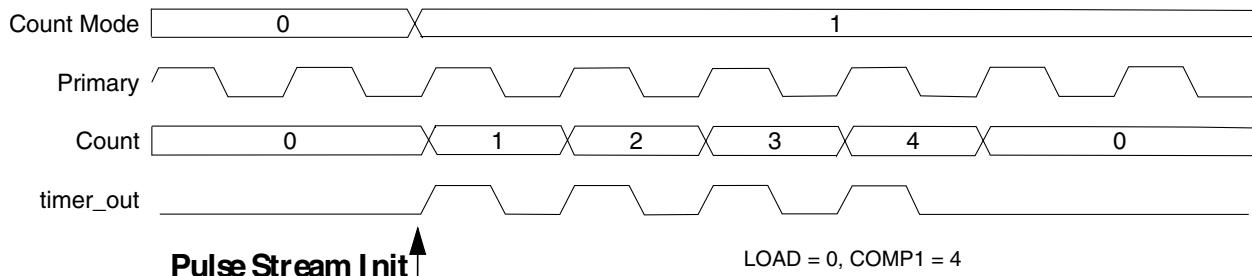

Figure 54-7. Pulse Output Mode

#### Example: 54.4.5.12.1 Pulse Outputs Using Two Counters

```

// This example generates six 10ms pulses, from QT1 output.
// Assuming the chip is operating at 60 MHz.
//
// To do this, timer 3 is used to generate a clock with a period of 10ms.
//
// Timer 1 is used to gate these clocks and count the number of pulses that have
// been generated.
//
void PulseStream_Init(void)
{
// Select IP_bus_clk/16 as the clock source for Timer 3

```

## Functional Description

```
/* TMR3_CTRL: CM=0,PCS=0x0C,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=3 */
setReg(TMR3_CTRL,0x1823); /* Set up mode */
/* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
   Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
setReg(TMR3_SCTRL,0x00);
setReg(TMR3_LOAD,0x00); /* Reset load register */
setReg(TMR3_COMP1,37500-1); /* (16 * 37500) / 60e6 = 0.01 sec */
/* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
setReg(TMR3_CSCTRL,0x00); /* Set up comparator control register */

// Timer 3 output is the clock source for this timer.
/* TMR1_CTRL: CM=0,PCS=7,SCS=0,ONCE=1,LENGTH=1,DIR=0,COINIT=0,OUTMODE=7 */
setReg(TMR1_CTRL,0x0E67); /* Set up mode */
/* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
   Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
setReg(TMR1_SCTRL,0x01);
setReg(TMR1_CNTR,0x00); /* Reset counter register */
setReg(TMR1_LOAD,0x00); /* Reset load register */
setReg(TMR1_COMP1,0x04); /* Set up compare 1 register */

// set to interrupt after the last pulse
/* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
   TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=0 */
setReg(TMR1_CSCTRL,0x40); /* Set up comparator control register */
// Finally, start the counters running
setReg(TMR3_CNTR,0); /* Reset counter */
setRegBitGroup(TMR3_CTRL,CM,0x01); /* Run source clock counter */
setRegBitGroup(TMR1_CTRL,CM,0x01); /* Run counter */
}
```

### 54.4.5.13 Fixed-Frequency PWM Mode

If CTRL[CM]=001, count through roll-over (CTRL[LENGTH]=0), continuous count (CTRL[ONCE]=0) and CTRL[OUTMODE] is '110' (set on compare, cleared on counter roll-over), then the counter output yields a pulse-width modulated (PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse-width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

#### Example: 54.4.5.13.1 Fixed-Frequency PWM Mode Example

```
// This example uses TMR0 for Fixed-Frequency PWM mode timing.
//
// The timer will count IP_bus clocks continuously until it rolls over.
// This results in a PWM period of 65536 / 60e6 = 1092.267 usec
//
// Initially, an output pulse width of 25 usec is generated ( 1500 / 60e6 )
// giving a PWM ratio of 1500 / 65536 = 2.289%
// This pulse width can be changed by changing the COMP1 register value (using CMPLD1).
//
void PWM1_Init(void)
{
    setReg(TMR0_CNTR,0); /* Reset counter */
    /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
       Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */
}
```

```

setReg(TMR0_SCTRL,0x05);           /* Enable output */
setReg(TMR0_COMP1,1500-1);         /* Store initial value to the duty-compare register */
/* TMR0_CTRL: CM=1,PCS=8,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=6 */
setReg(TMR0_CTRL,0x3006);          /* Run counter */
}

```

#### 54.4.5.14 Variable-Frequency PWM Mode

If CTRL[CM]=001, count until compare (CTRL[LENGTH]=1), continuous count (CTRL[ONCE] = 0) and CTRL[OUTMODE] is '100' (toggle OFLAG and alternate compare registers), then the counter output yields a pulse-width modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

To set up the TMR to run in variable frequency PWM mode with compare preload please use the following setup for the specific counter you would like to use. When performing the setup, update the TMR\_CTRL register last because the counter will start counting if the count mode is changed to any value other than 000 (assuming the primary count source is already active).

#### Timer Control Register (CTRL)

- CM=001 (count rising edges of primary source)
- PCS=1000 (IP bus clock for best granularity for waveform timing)
- SCS=Any (ignored in this mode)
- ONCE=0 (want to count repeatedly)
- LENGTH=1 (want to count until compare value is reached and re-initialize counter register)
- DIR=Any (user's choice. The compare register values must be chosen carefully to account for things like roll-under, etc.)
- COINIT=0 (user can set this if they need this function)
- OUTMODE=100 (toggle OFLAG output using alternating compare registers)

#### Timer Status and Control Register (SCTRL)

## Functional Description

- OEN = 1 (output enable to allow OFLAG output to be put on an external pin. Set this bit as needed.)
- OPS = Any (user's choice)
- Make sure the rest of the bits are cleared for this register. We will enable interrupts in the comparator status and control register instead of in this register.

## Comparator Status and Control Register (CSCTRL)

- TCF2EN=1 (allow interrupt to be issued when CSCTRL[TCF2] is set)
- TCF1EN=0 (do not allow interrupt to be issued when CSCTRL[TCF1] is set)
- TCF1=0 (clear timer compare 1 interrupt source flag. This is set when counter register equals compare register 1 value and OFLAG is low)
- TCF2=0 (clear timer compare 2 interrupt source flag. This is set when counter register equals compare register 2 value and OFLAG is high)
- CL1=10 (load compare register when CSCTRL[TCF2] is asserted)
- CL2=01 (load compare register when CSCTRL[TCF1] is asserted)

## Interrupt Service Routines

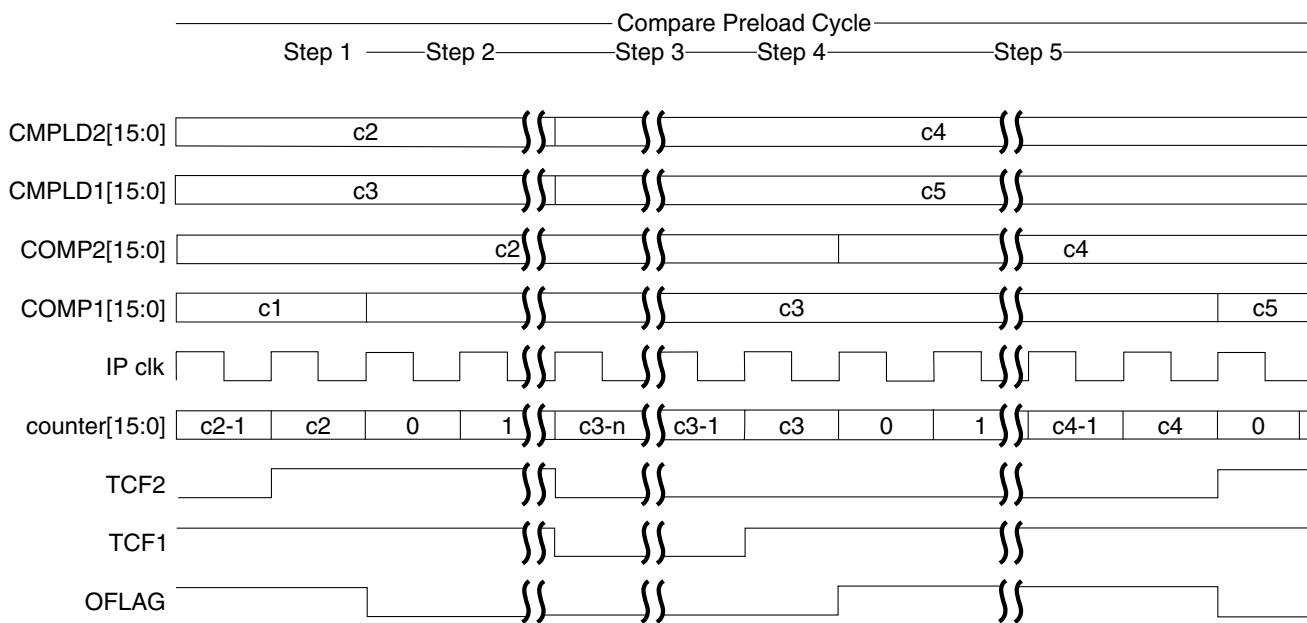

To service the CSCTRL[TCF2] interrupts generated by the timer, the interrupt controller must be configured to enable the interrupts for the particular timer being used.

Additionally the user will need to write an interrupt service routine to do at a minimum the following:

- Clear CSCTRL[TCF2] and CSCTRL[TCF1] flags.
- Calculate and write new values for both CMPLD1 and CMPLD2.

## Timing

This figure contains the timing for using the compare preload feature. The compare preload cycle begins with a compare event on COMP2 causing CSCTRL[TCF2] to be asserted. COMP1 is loaded with the value in the CMPLD1 (c3) one IP bus clock later. In addition an interrupt is asserted by the timer and the interrupt service routine is executed during which both comparator load registers are updated with new values (c4 and c5). When CSCTRL[TCF1] is asserted, COMP2 is loaded with the value in CMPLD2 (c4). And on the subsequent CSCTRL[TCF2] event, COMP1 is loaded with the value in CMPLD1 (c5). The cycle starts over again as an interrupt is asserted and the interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and calculates new values for CMPLD1 and CMPLD2.

Step 1-- CNTR matches COMP2 value. CSCTRL[TCF2] is asserted and an interrupt request is generated.

Step 2-- One clock later, OFLAG toggles, CMPLD1 is copied to COMP1, LOAD is copied to CNTR, the counter starts counting.

Step 3-- The interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and the ISR loads CMPLD1 and CMPLD2 with the values for the next cycle. The counter continues counting until CNTR matches COMP1.

Step 4-- CSCTRL[TCF1] is asserted. One clock later, OFLAG toggles, CMPLD2 is copied to COMP2, LOAD is copied to CNTR and the counter starts counting.

Step 5--The counter continues counting until CNTR matches COMP2.

**Figure 54-8. Compare Load Timing**

### Example: 54.4.5.14.1 Variable Frequency PWM Mode

```
// This example starts with an 11 msec with a 31 msec cycle.
// Assuming the chip is operating at 60 MHz, the timer use IP_bus_clk/32 as its
// clock source.
//
// Initial pulse period: 60e6/32 clocks/sec * 31 ms = 58125 total clocks in period
// Initial pulse width: 60e6/32 clocks/sec * 11 ms = 20625 clocks in pulse
//
//
// Once the initial values of COMP1/CMPLD1 and COMP2/CMPLD2 are set the pulse width
// can be varied by load new values of CMPLD1 and CMPLD2 on each compare interrupt.
// (See Usage of Compare Load Registers.)
//
void PPG1_Init(void)
{
    setReg(TMRO_LOAD, 0);           /* Clear load register */
    setReg(TMRO_CNTR, 0);          /* Clear counter */
}
```

## Resets

```
/* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,  
   Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */  
setReg(TMR0_SCTRL,5); /* Set Status and Control Register */  
// Set compare preload operation and enable an interrupt on compare2 events.  
/* TMR0_CSCTRL: TCF2EN=1,TCF1EN=0,TCF2=0,TCF1=0,CL21=0,CL20=1,CL11=1,CL10=0 */  
setReg(TMR0_CSCTRL,0x86); /* Set Comparator Status and Control Register */  
  
setReg(TMR0_COMP1, 20625-1); /* Set the pulse width of the off time */  
setReg(TMR0_CMPLD1,20625-1); /* Set the pulse width of the off time */  
setReg(TMR0_COMP2, 58125-20625-1); /* Set the pulse width of the on time */  
setReg(TMR0_CMPLD2,58125-20625-1); /* Set the pulse width of the on time */  
/* TMR0_CTRL: CM=1,PCS=0xD,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=4 */  
setRegBits(TMR0_CTRL,0x3A24); /* Set variable PWM mode and run counter */  
}
```

## 54.5 Resets

### 54.5.1 General

The TMR module can be reset only by the RST\_B signal. This forces all registers to their reset state and clears the OFLAG signal if it is asserted. The counter will be turned off until the settings in the control register are changed.

**Table 54-2. Reset Summary**

Reset	Priority	Source	Characteristics
RST_B	n/a	Hardware Reset	Full System Reset

## 54.6 Clocks

### 54.6.1 General

The timer only receives BUS\_CLK\_ROOT .

## 54.7 Interrupts

## 54.7.1 General

The TMR module can generate 20 interrupts, Five for each of the four counters/channels.

**Table 54-3. Interrupt Summary**

Core Interrupt	Interrupt	Description
TMR Channel 0	TMR0_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 0
	TMR0_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 0
	TMR0_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 0
	TMR0_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 0
	TMR0_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 0
TMR Channel 1	TMR1_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 1
	TMR1_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 1
	TMR1_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 1
	TMR1_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 1
	TMR1_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 1
TMR Channel 2	TMR2_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 2
	TMR2_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 2
	TMR2_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 2
	TMR2_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 2
	TMR2_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 2
TMR Channel 3	TMR3_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 3
	TMR3_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 3
	TMR3_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 3
	TMR3_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 3
	TMR3_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 3

Overflow interrupts do not work if counting upward - Errata ERR050194

## 54.7.2 Description of Interrupt Operation

### 54.7.2.1 Timer Compare Interrupts

These interrupts are generated when a successful compare occurs between a counter and its compare registers while SCTRL[TCFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[TCF].

When a timer compare interrupt is set in TMR\_SCTRL and the Compare Load registers are available, one of the following two interrupts will also be asserted.

#### 54.7.2.1.1 Timer Compare 1 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP1 register while CSCTRL[TCF1EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF1].

#### 54.7.2.1.2 Timer Compare 2 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP2 register while CSCTRL[TCF2EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF2].

#### 54.7.2.2 Timer Overflow Interrupts

These interrupts are generated when a counter rolls over its maximum value while SCTRL[TOFIE] is set. These interrupts are cleared by writing zero to the appropriate SCTRL[TOF].

#### 54.7.2.3 Timer Input Edge Interrupts

These interrupts are generated by a transition of the input signal (either positive or negative depending on IPS setting) while SCTRL[IEFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[IEF].

### 54.8 DMA

The TMR module can generate twelve DMA requests: three for each of the four counters/channels. Refer to the following table.

**Table 54-4. DMA Summary**

DMA Request	DMA Enable	Description
Channels 0-3	DMA[IEFDE]	CAPT contains a value
	DMA[CMPLD1DE]	CMPLD1 needs an update
	DMA[CMPLD2DE]	CMPLD2 needs an update

## 54.9 Memory map/register definition

### 54.9.1 TMR register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. Make certain to check which quad timer is available on the chip being used, and which timer channels have external I/O.

#### 54.9.1.1 TMR memory map

TMR1 base address: 401D\_C000h

TMR2 base address: 401E\_0000h

TMR3 base address: 401E\_4000h

TMR4 base address: 401E\_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Timer Channel Compare Register 1 (COMP10)	16	RW	0000h

### 54.9.1.8.2 Diagram

### 54.9.1.8.3 Fields

Field	Function
15-13 CM	<p>Count Mode</p> <p>These bits control the basic counting and behavior of the counter.</p> <ul style="list-style-type: none"> <li>000b - No operation</li> <li>001b - Count rising edges of primary source<sup>1</sup></li> <li>010b - Count rising and falling edges of primary source<sup>2</sup></li> <li>011b - Count rising edges of primary source while secondary input high active</li> <li>100b - Quadrature count mode, uses primary and secondary sources</li> <li>101b - Count rising edges of primary source; secondary source specifies direction<sup>3</sup></li> <li>110b - Edge of secondary source triggers primary count until compare</li> <li>111b - Cascaded counter mode (up/down)<sup>4</sup></li> </ul>
12-9 PCS	<p>Primary Count Source</p> <p>These bits select the primary count source.</p> <p><b>NOTE:</b> A timer selecting its own output for input is not a legal choice. The result is no counting.</p> <p>0000b - Counter 0 input pin</p>

Table continues on the next page...

## Memory map/register definition

Field	Function
	0001b - Counter 1 input pin 0010b - Counter 2 input pin 0011b - Counter 3 input pin 0100b - Counter 0 output 0101b - Counter 1 output 0110b - Counter 2 output 0111b - Counter 3 output 1000b - IP bus clock divide by 1 prescaler 1001b - IP bus clock divide by 2 prescaler 1010b - IP bus clock divide by 4 prescaler 1011b - IP bus clock divide by 8 prescaler 1100b - IP bus clock divide by 16 prescaler 1101b - IP bus clock divide by 32 prescaler 1110b - IP bus clock divide by 64 prescaler 1111b - IP bus clock divide by 128 prescaler
8-7 SCS	<b>Secondary Count Source</b> These bits identify the external input pin to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of CNTR . The selected input can also be used to specify the count direction. The selected signal can also be used as a fault input when CSCTRL[FAULT] is set. The polarity of the signal can be inverted by SCTRL[IPS].
6 ONCE	<b>Count Once</b> This bit selects continuous or one shot counting mode. 0b - Count repeatedly. 1b - Count until compare and then stop. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode \$4 is used, the counter re-initializes after reaching the COMP1 value, continues to count to the COMP2 value, and then stops.
5 LENGTH	<b>Count Length</b> This bit determines whether the counter: <ul style="list-style-type: none"> <li>• counts to the compare value and then re-initializes itself to the value specified in the LOAD (or CMPLD2) register, or</li> <li>• continues counting past the compare value to the binary roll over.</li> </ul> 0b - Count until roll over at \$FFFF and continue from \$0000. 1b - Count until compare, then re-initialize. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode \$4 is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until a COMP1 value is reached, re-initializes, counts until COMP2 value is reached, re-initializes, counts until COMP1 value is reached, and so on.
4 DIR	<b>Count Direction</b> This bit selects either the normal count direction up, or the reverse direction, down. 0b - Count up. 1b - Count down.
3 COINIT	<b>Co-Channel Initialization</b> This bit enables another counter/timer within the module to force the re-initialization of this counter/timer when it has an active compare event.

*Table continues on the next page...*

Field	Function
	0b - Co-channel counter/timers cannot force a re-initialization of this counter/timer 1b - Co-channel counter/timers may force a re-initialization of this counter/timer
2-0 OUTMODE	<p>Output Mode</p> <p>These bits determine the mode of operation for the OFLAG output signal.</p> <ul style="list-style-type: none"> <li>000b - Asserted while counter is active</li> <li>001b - Clear OFLAG output on successful compare</li> <li>010b - Set OFLAG output on successful compare</li> <li>011b - Toggle OFLAG output on successful compare</li> <li>100b - Toggle OFLAG output using alternating compare registers</li> <li>101b - Set on compare, cleared on secondary source input edge</li> <li>110b - Set on compare, cleared on counter rollover</li> <li>111b - Enable gated clock output while counter is active</li> </ul>

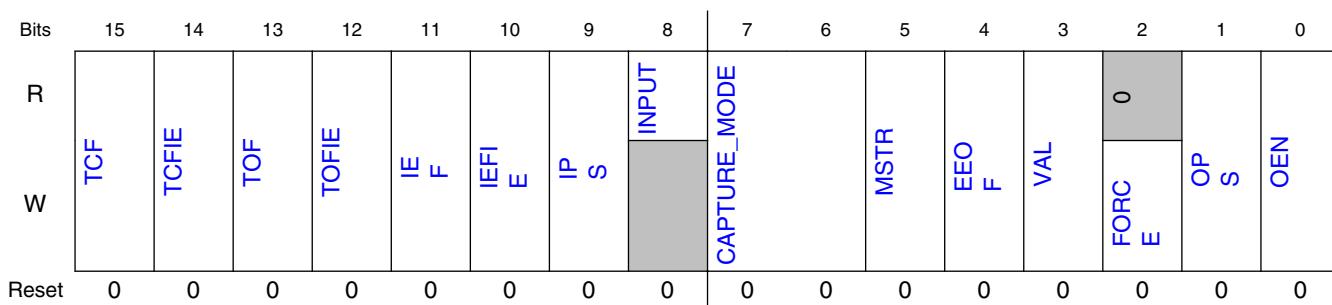

1. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1. If the primary count source is IP bus clock divide by 1, only rising edges are counted regardless of the value of SCTRL[IPS].
2. IP bus clock divide by 1 cannot be used as a primary count source in edge count mode.
3. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1.
4. The primary count source must be set to one of the counter outputs.

### 54.9.1.9 Timer Channel Status and Control Register (SCTRL0 - SCTRL3)

#### 54.9.1.9.1 Offset

Register	Offset
SCTRL0	Eh
SCTRL1	2Eh
SCTRL2	4Eh
SCTRL3	6Eh

#### 54.9.1.9.2 Diagram

### 54.9.1.9.3 Fields

Field	Function
15 TCF	Timer Compare Flag This bit is set when a successful compare occurs. This bit is cleared by writing a zero to this bit location.
14 TCFIE	Timer Compare Flag Interrupt Enable <b>Can use compare with 0xFFFF as workaround for TOF</b> This bit (when set) enables interrupts when TCF is set.
13 TOF	Timer Overflow Flag <b>This bit is never set if counting upward - Errata ERR050144</b> This bit is set when the counter rolls over its maximum value \$FFFF or \$0000 (depending on count direction). This bit is cleared by writing a zero to this bit location.
12 TOFIE	Timer Overflow Flag Interrupt Enable This bit (when set) enables interrupts when TOF is set.
11 IEF	Input Edge Flag This bit is set when CAPTMODE is enabled and a proper input transition occurs (on an input selected as a secondary count source) while the count mode does not equal 000. This bit is cleared by writing a zero to this bit position. This bit can also be cleared automatically by a read of CAPT when DMA[IEFDE] is set. <b>NOTE:</b> Setting the input polarity select bit (IPS) changes the edge to be detected. Also, the control register's secondary count source determines which external input pin is monitored by the detection circuitry.
10 IEFIE	Input Edge Flag Interrupt Enable This bit (when set) enables interrupts when IEF is set. <b>Restriction:</b> Do not set both this bit and DMA[IEFDE].
9 IPS	Input Polarity Select This bit (when set) inverts the input signal polarity.
8 INPUT	External Input Signal This read-only bit reflects the current state of the external input pin selected via the secondary count source after application of IPS and filtering.
7-6 CAPTURE_MODE	Input Capture Mode These bits specify the operation of the capture register as well as the operation of the input edge flag. The input source is the secondary count source. 00b - Capture function is disabled 01b - Load capture register on rising edge (when IPS=0) or falling edge (when IPS=1) of input 10b - Load capture register on falling edge (when IPS=0) or rising edge (when IPS=1) of input 11b - Load capture register on both edges of input
5 MSTR	Master Mode This bit (when set) enables the compare function's output to be broadcasted to the other counters/timers in the module. This signal then can be used to re-initialize the other counters and/or force their OFLAG signal outputs.
4 EEOF	Enable External OFLAG Force This bit (when set) enables the compare from another counter/timer within the same module to force the state of this counter's OFLAG output signal.
3 VAL	Forced OFLAG Value This bit determines the value of the OFLAG output signal when software triggers a FORCE command.
2 FORCE	Force OFLAG Output

Table continues on the next page...

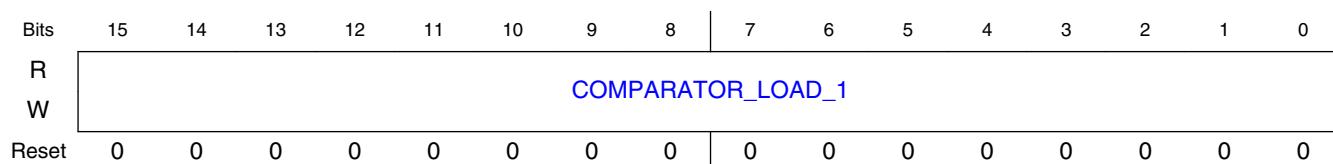

Field	Function
	This write only bit forces the current value of VAL to be written to the OFLAG output. This bit always reads as a zero. VAL and FORCE can be written simultaneously in a single write operation. Write to FORCE only if the counter is disabled. Setting this bit while the counter is enabled may yield unpredictable results.
1 OPS	Output Polarity Select  This bit determines the polarity of the OFLAG output signal.  0b - True polarity. 1b - Inverted polarity.
0 OEN	Output Enable  This bit determines the direction of the external pin.  0b - The external pin is configured as an input. 1b - The OFLAG output signal is driven on the external pin. Other timer groups using this external pin as their input see the driven value. The polarity of the signal is determined by OPS.

### 54.9.1.10 Timer Channel Comparator Load Register 1 (CMPLD10 - CMPLD13)

#### 54.9.1.10.1 Offset

Register	Offset

### 54.9.1.12.2 Diagram

### 54.9.1.12.3 Fields

Field	Function
15-14 DBG_EN	Debug Actions Enable These bits allow the TMR module to perform certain actions in response to the chip entering debug mode. 00b - Continue with normal operation during debug mode. (default) 01b - Halt TMR counter during debug mode. 10b - Force TMR output to logic 0 (prior to consideration of SCTRL[OPS]). 11b - Both halt counter and force output to 0 during debug mode.
13 FAULT	Fault Enable The selected secondary input acts as a fault signal so that the timer OFLAG is cleared when the secondary input is set. When the secondary input is used in this mode, there is no resynchronization of the input so that there is a combinational path to clear the OFLAG. Fault inputs less than two clock periods wide will not be latched. Latched faults will be cleared the next time that the counter logic sets the OFLAG. 0b - Fault function disabled. 1b - Fault function enabled.
12 ALT_LOAD	Alternative Load Enable This bit allows for an alternative method for loading the counter during modulo counting. Normally, the counter can be loaded only with the value from the LOAD register. When this bit is set, the counter is loaded from the LOAD register when counting up and a match with COMP1 occurs, or the counter is loaded from the CMPLD2 register when counting down and a match with COMP2 occurs. 0b - Counter can be re-initialized only with the LOAD register. 1b - Counter can be re-initialized with the LOAD or CMPLD2 registers depending on count direction.
11 ROC	Reload on Capture This bit enables the capture function to cause the counter to be reloaded from the LOAD register. 0b - Do not reload the counter on a capture event. 1b - Reload the counter on a capture event.
10	Triggered Count Initialization Control

Register	Offset
FILT0	16h
FILT1	36h
FILT2	56h
FILT3	76h

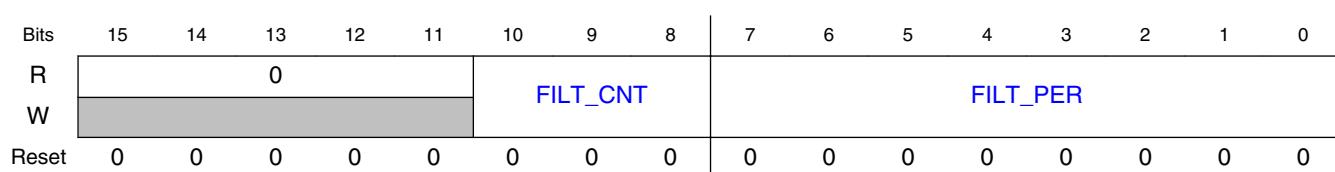

### 54.9.1.13.2 Function

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any timer channel can use the input as a count source.

Input filter considerations:

- Set the FILT\_PER value such that the sampling period is larger than the period of the expected noise. In this way, a noise spike will corrupt only one sample. Choose the FILT\_CNT value to reduce the probability that noisy samples cause an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of (FILT\_CNT + 3).
- The values of FILT\_PER and FILT\_CNT must also be balanced against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT\_PER to a non-zero value) introduces a latency of (((FILT\_CNT + 3) x FILT\_PER) + 2) IP bus clock periods.

#### NOTE

In this device, PWM<sub>x</sub>\_EXTB is not applicable. It also does not support external ADC input. Also there is **no** NanoEdge placement block in this device.

#### NOTE

PWM\_X only applicable to FlexPWM1, while other FlexPWM instances do not have the PWMX outputs or inputs.

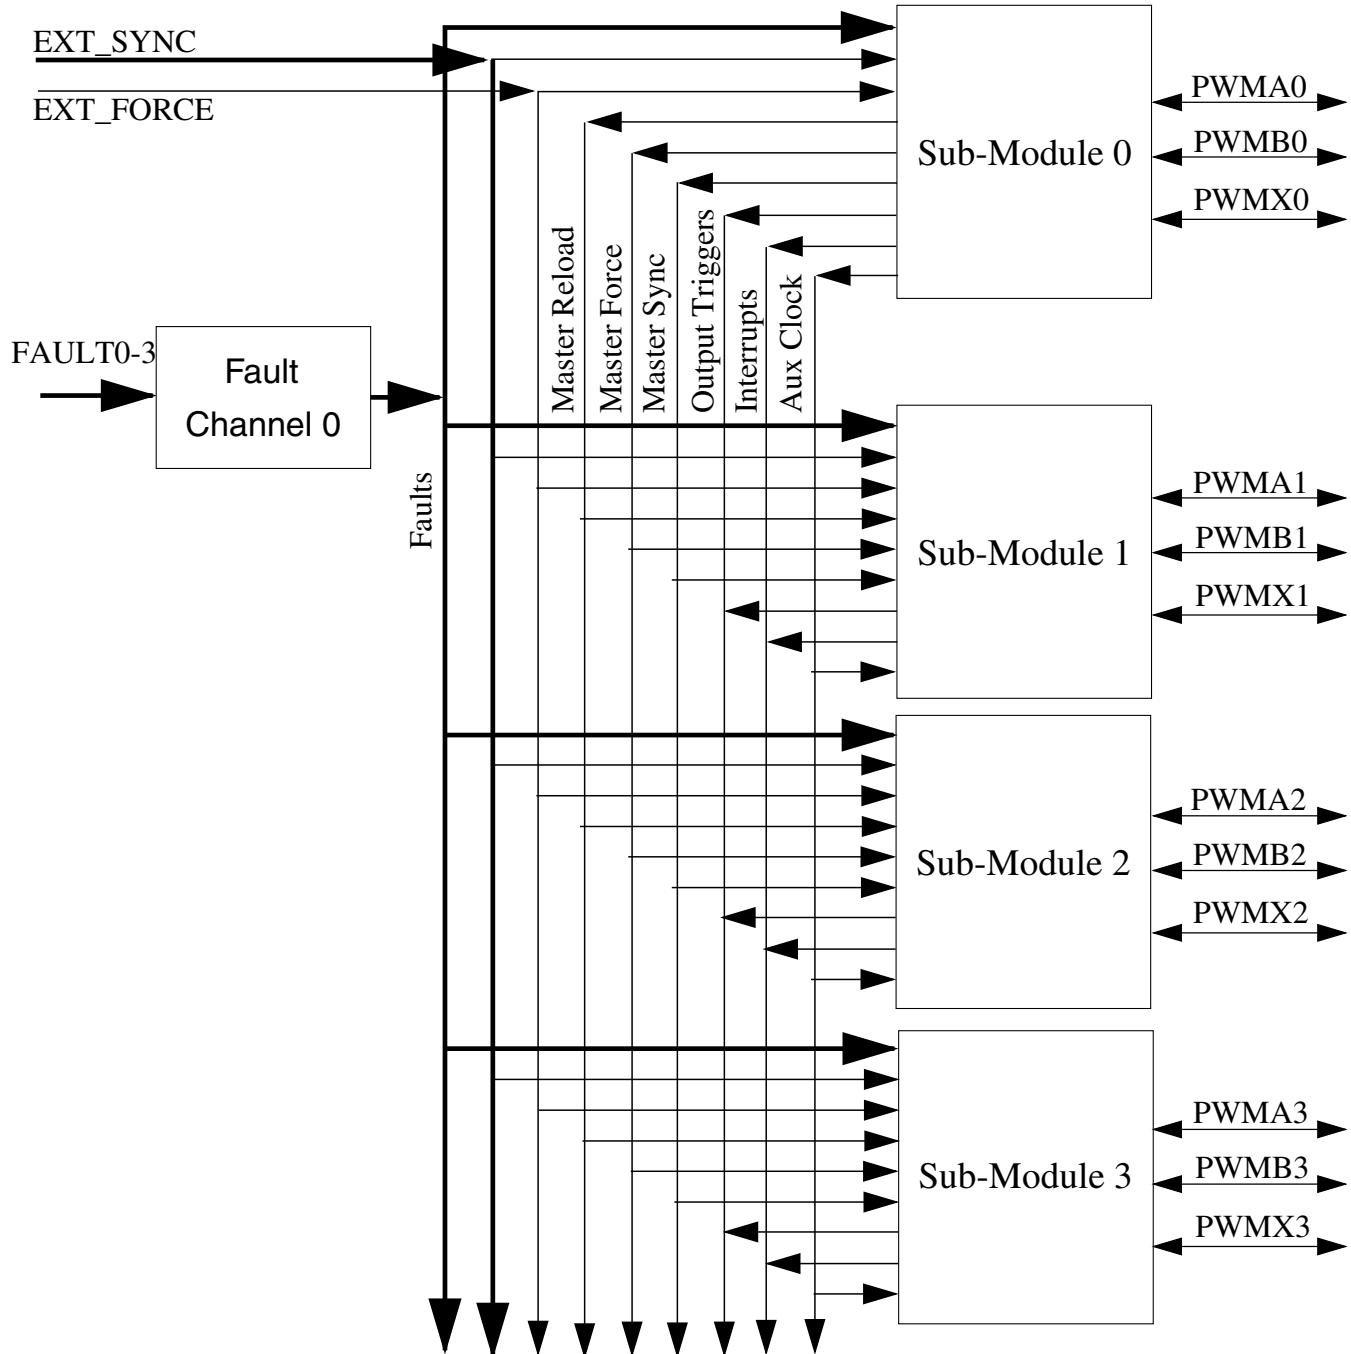

### 55.2 Overview

The pulse width modulator (PWM) module contains PWM submodules, each of which is set up to control a single half-bridge power stage. Fault channel support is provided.

This PWM module can generate various switching patterns, including highly sophisticated waveforms. It is ideal for controlling different Switched Mode Power Supplies (SMPS) topologies.

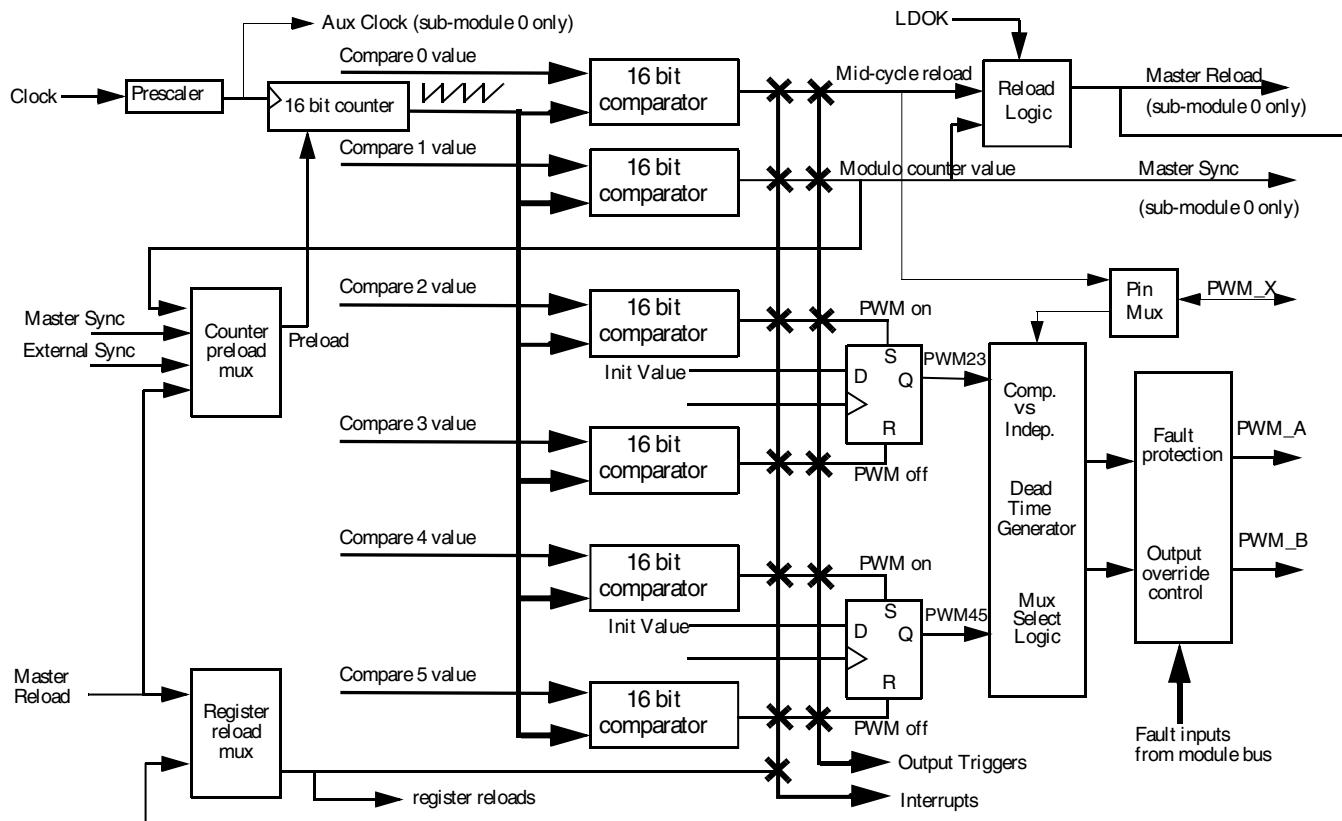

### 55.2.1 Block Diagram

The following figure is a block diagram of the PWM.

**Figure 55-1. PWM Block Diagram**

### 55.2.1.1 PWM Submodule

**Figure 55-2. PWM Submodule Block Diagram**

### 55.2.2 Features

- 16 bits of resolution for center, edge-aligned, and asymmetrical PWMs
- Fractional PWM clock generation for enhanced resolution of the PWM period and duty cycle
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs

- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE\_OUT event
- PWM\_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Enhanced dual edge capture functionality

### 55.2.3 Modes of operation

Be careful when using this module in Stop, Wait and Debug operating modes.

#### **CAUTION**

Some applications require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in Stop mode, and they can optionally be placed in inactive states in Wait and Debug modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

**Table 55-2. Modes when PWM Operation is Restricted**

Mode	Description
Stop	PWM outputs are inactive.
Wait	PWM outputs are driven or inactive as a function of CTRL2[WAITEN].
Debug	CPU and peripheral clocks continue to run, but the CPU may stall for periods of time. PWM outputs are driven or inactive as a function of CTRL2[DBGEN].

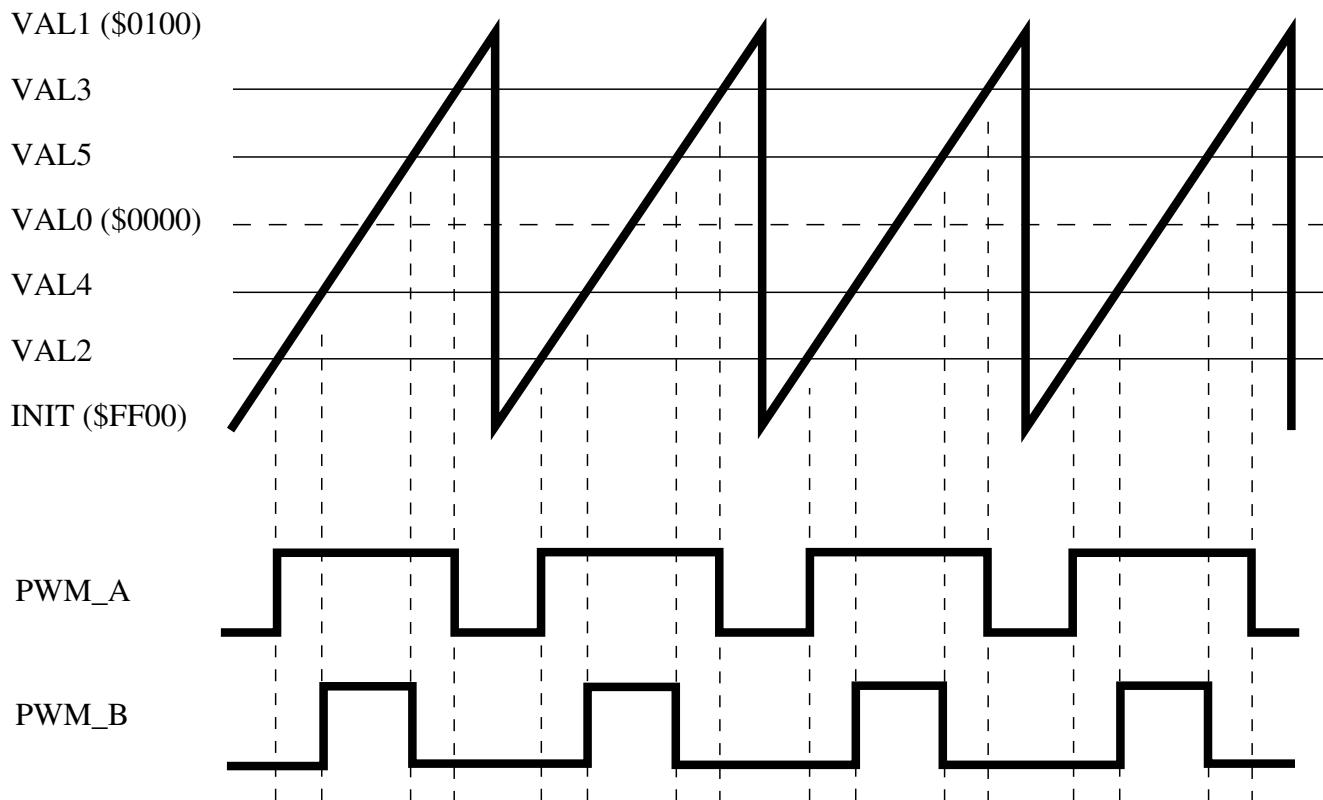

## 55.3 Functional Description

## 55.3.1 PWM Capabilities

This section describes some capabilities of the PWM module.

### 55.3.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in [Figure 55-3](#).

**Figure 55-3. Center Aligned Example**

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

[Figure 55-3](#) also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then

the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

### 55.3.1.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as the following figure shows. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

VAL1 (\$0100)

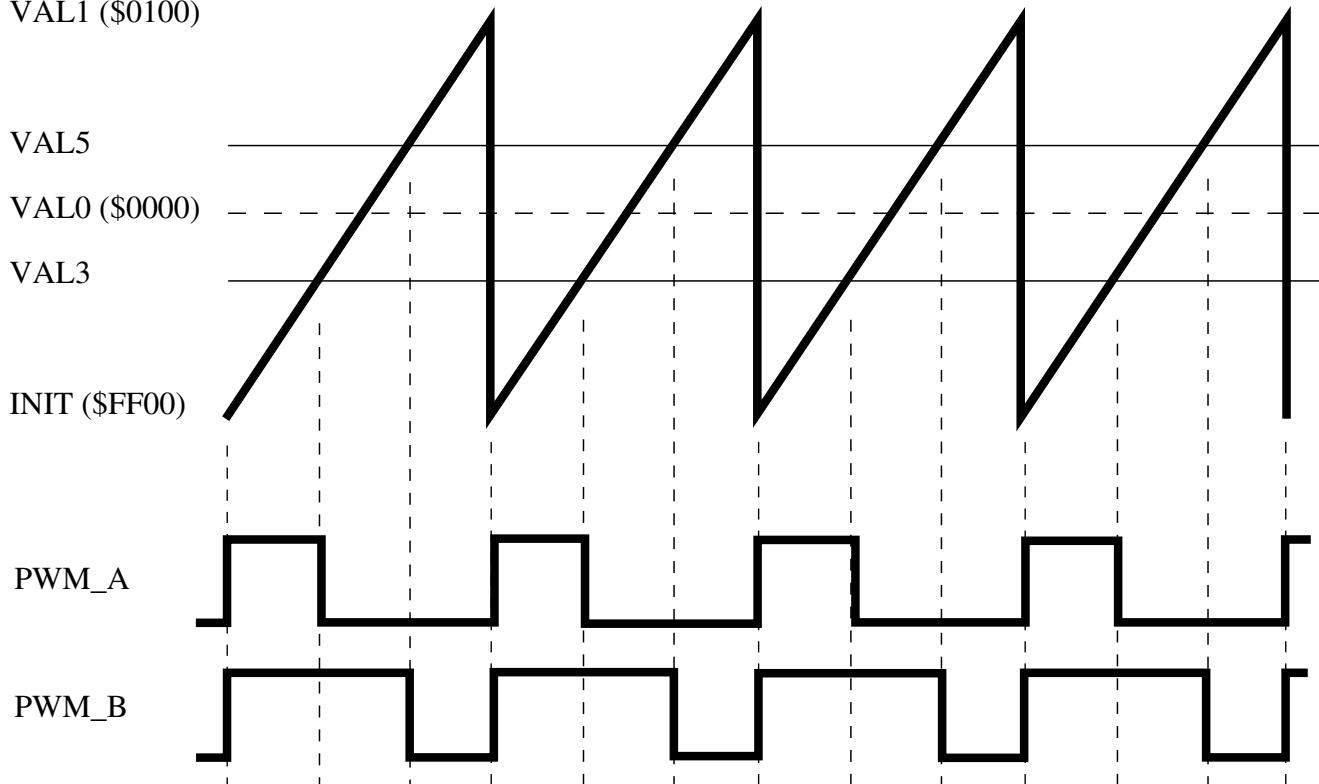

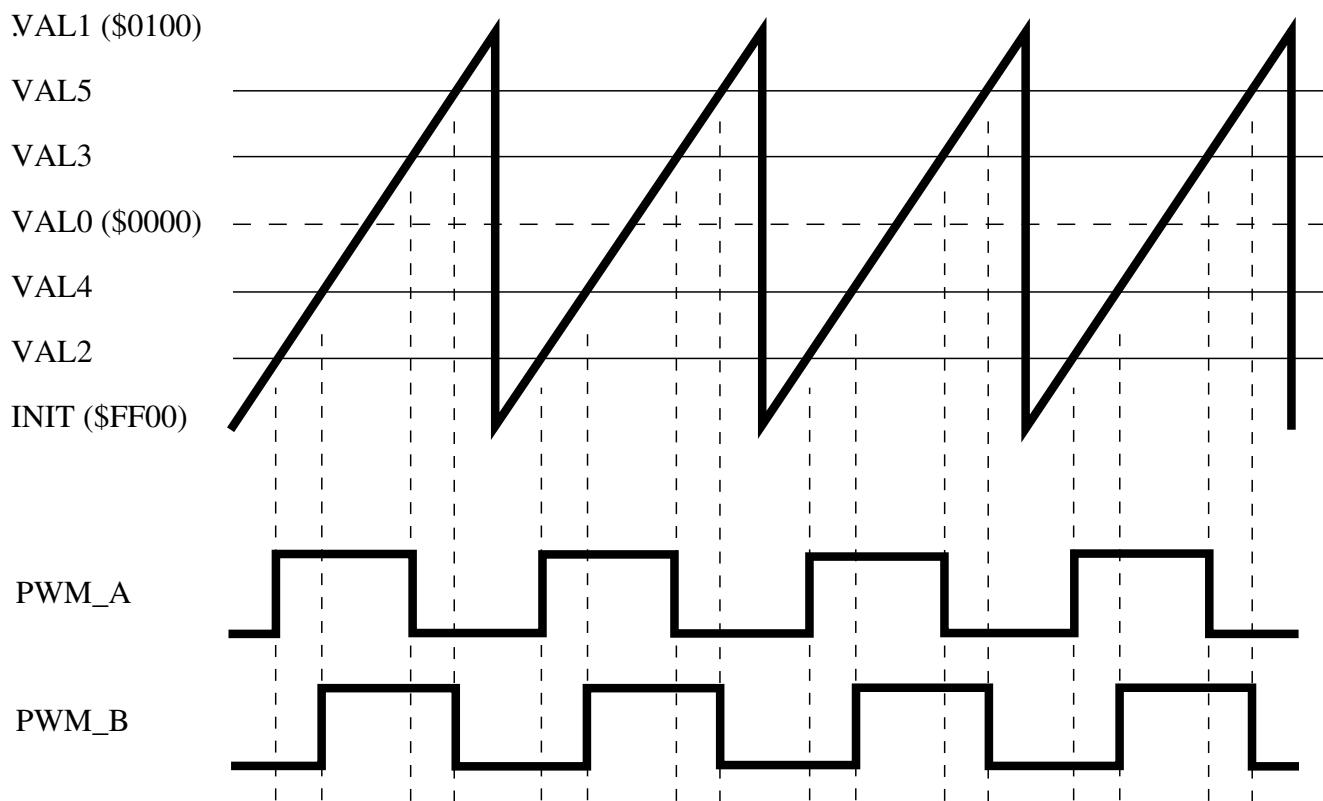

Figure 55-4. Edge Aligned Example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the motor inverter voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

### 55.3.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as the following figure shows. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

## Functional Description

**Figure 55-5. Phase Shifted Outputs Example**

An additional benefit of phase shifted PWMs appears in [Figure 55-6](#). In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

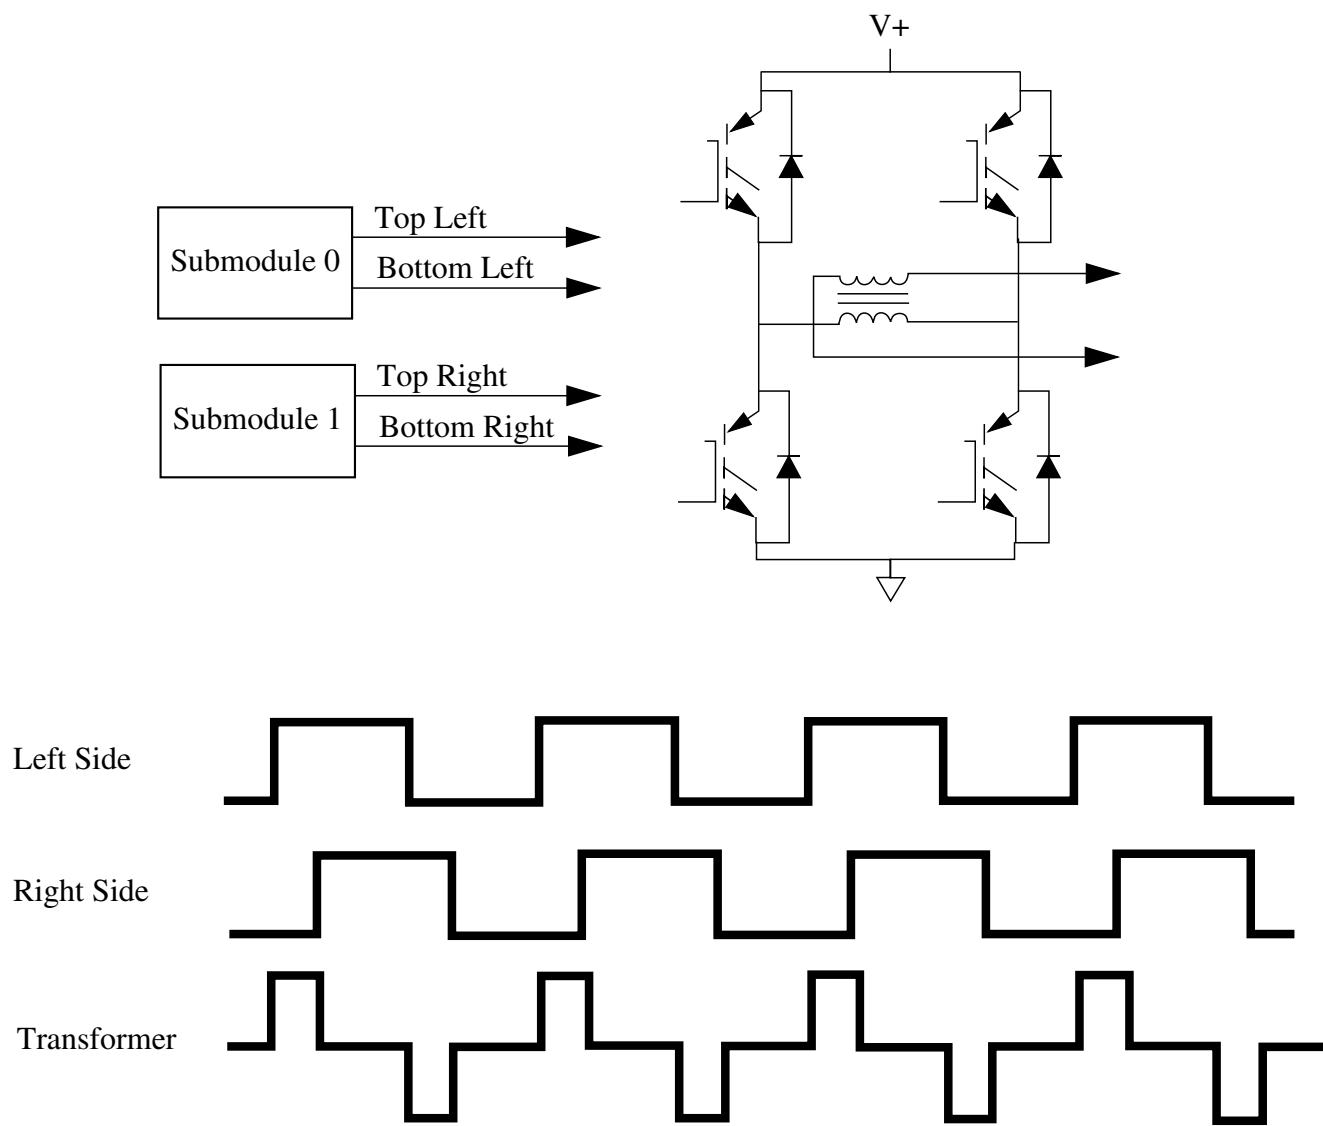

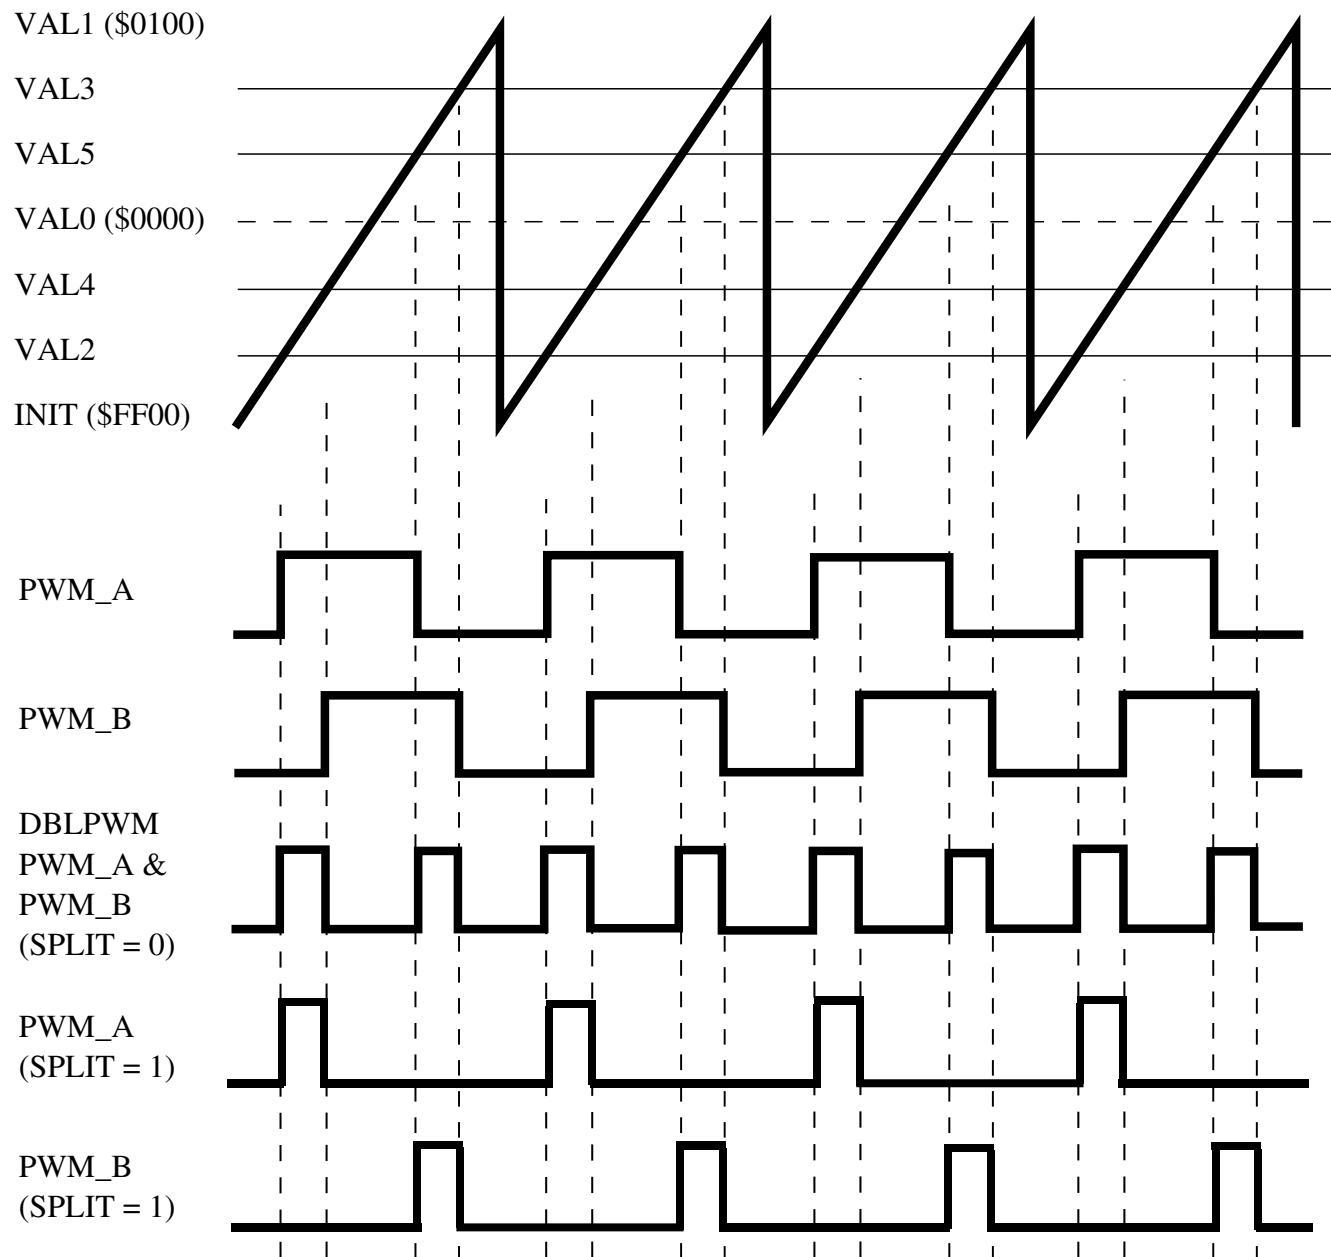

Figure 55-6. Phase Shifted PWMs Applied to a Transformer Primary

#### 55.3.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method supports two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWM\_A in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

## Functional Description

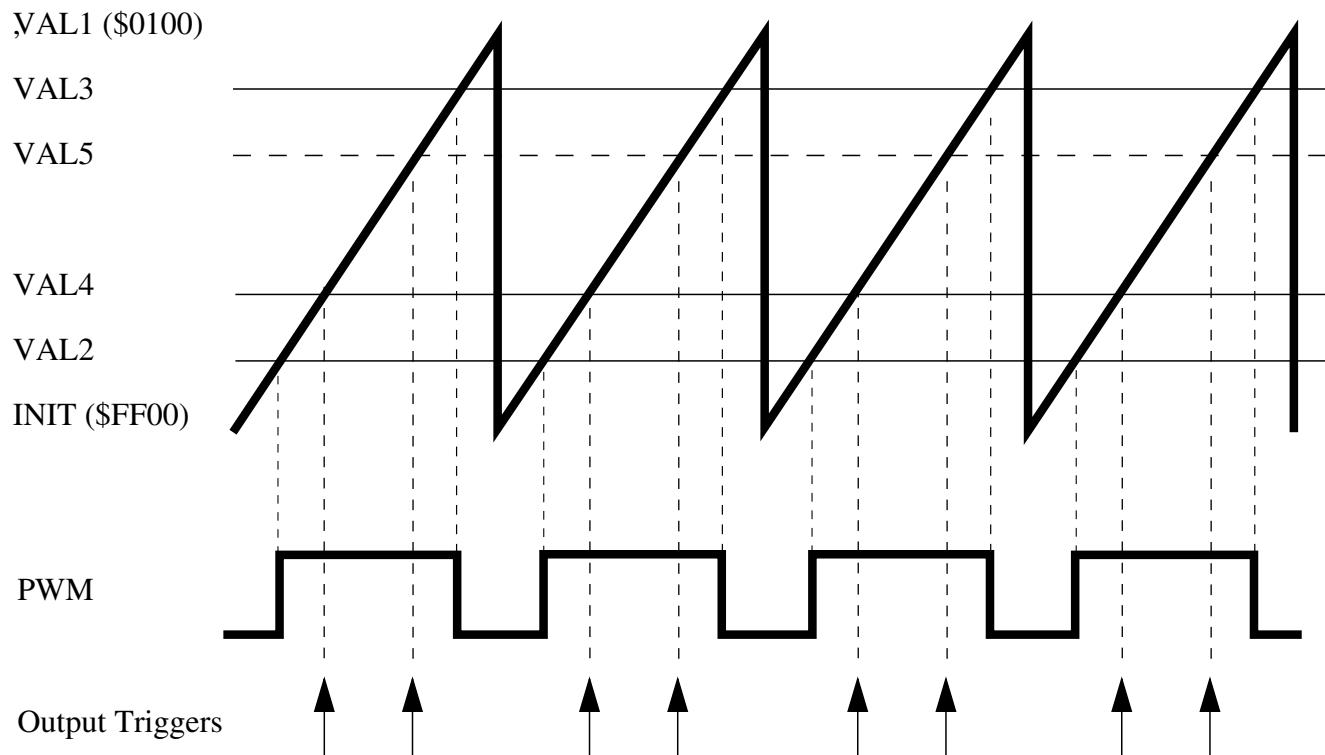

**Figure 55-7. Double Switching Output Example**

### 55.3.1.5 ADC Triggering

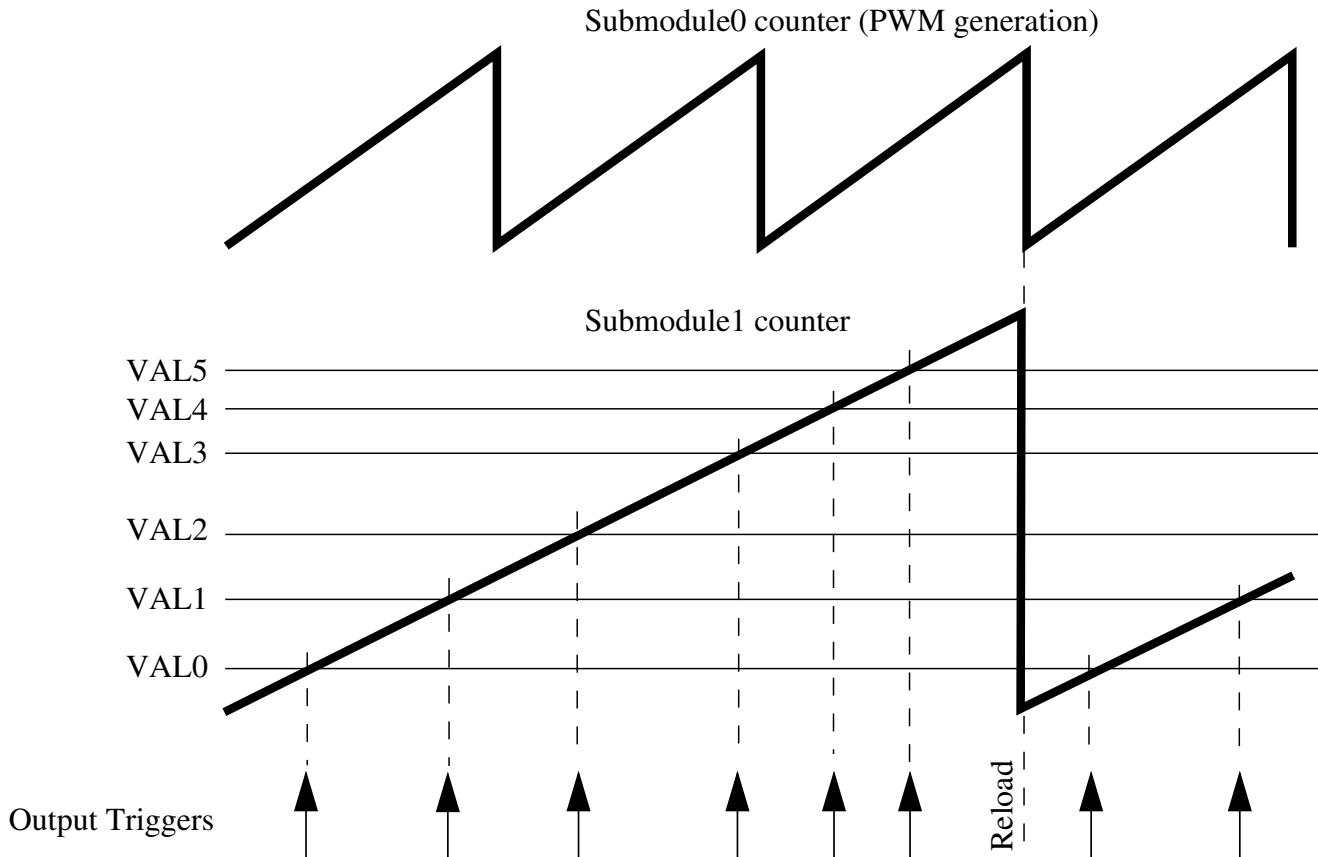

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. [Figure 55-8](#) shows how this is accomplished. When specifying complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators

are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

**Figure 55-8. Multiple Output Trigger Generation in Hardware**

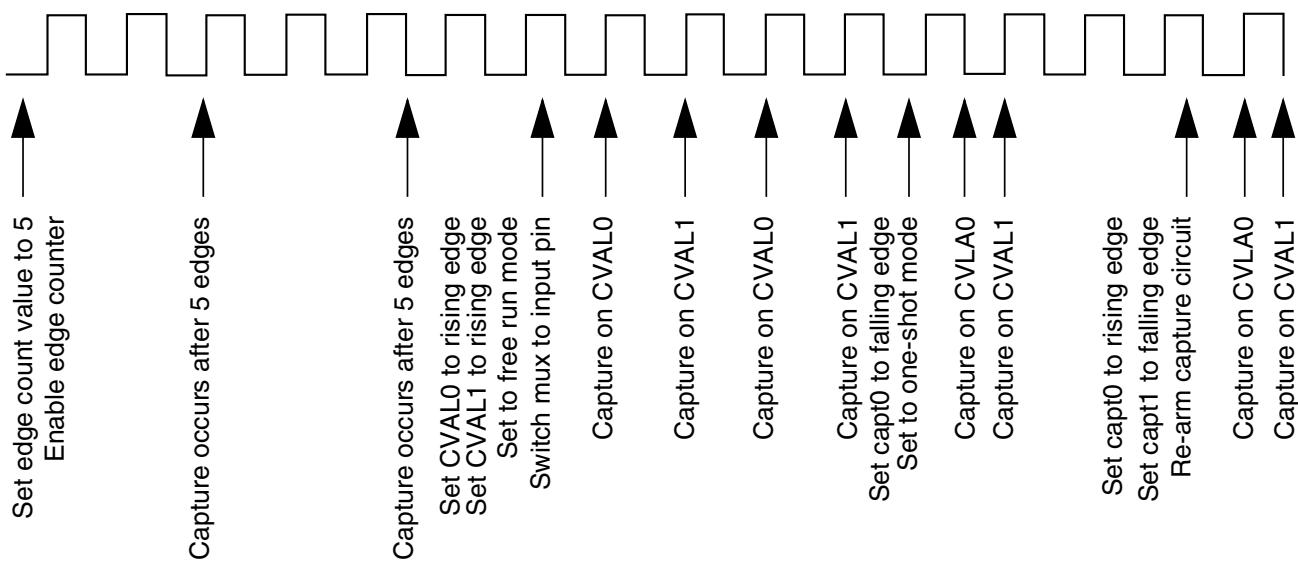

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. [Figure 55-9](#) shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In [Figure 55-9](#), all submodule comparators are shown being used for ADC trigger generation.

**Figure 55-9. Multiple Output Triggers Over Several PWM Cycles**

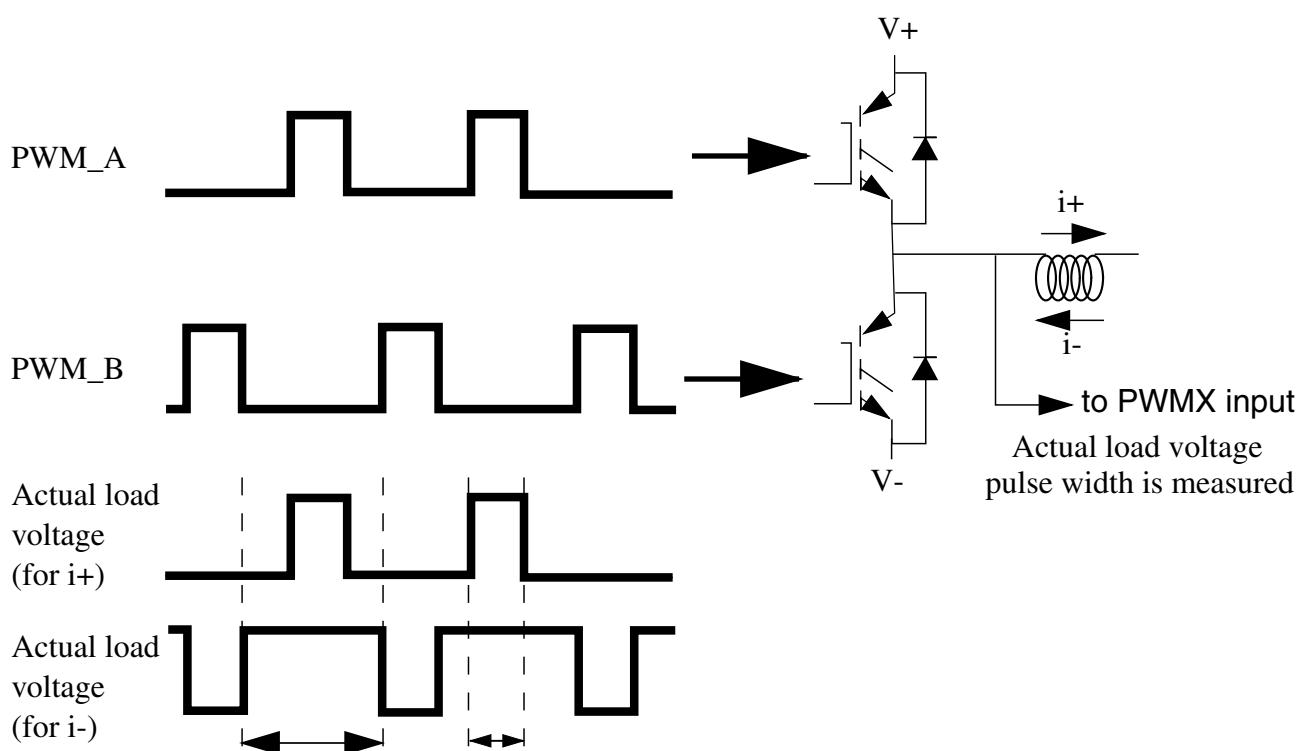

### 55.3.1.6 Enhanced Capture Capabilities (E-Capture)

When a PWM pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

**Figure 55-10. Capture Capabilities of the E-Capture Circuit**

When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM\_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. Consider the following figure as an example. In this application the output of a PWM power stage is connected to the PWM\_X pin that is configured for free running input captures. Specifically, the CVVAL0 capture circuitry is programmed for rising edges and the CVVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVVAL0 register value from the CVVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.

During deadtime, load inductance drives voltage with polarity that keeps inductive current flowing through diodes.

**Figure 55-11. Output Pulse Width Measurement Possible with the E-Capture Circuit**

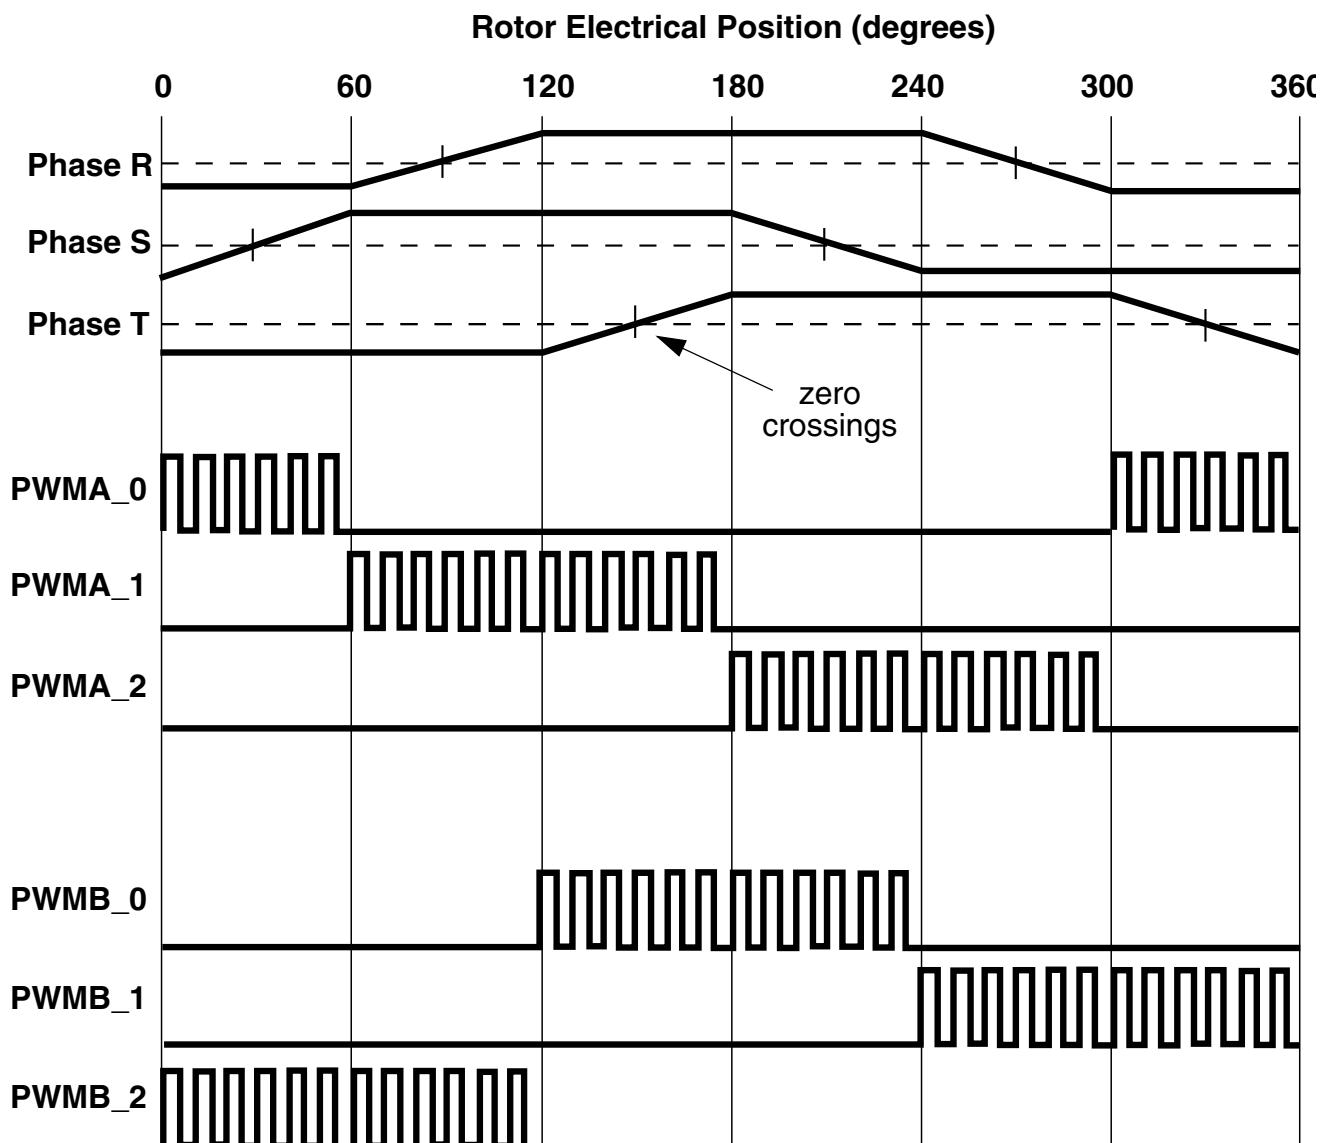

### 55.3.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called FORCE\_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE\_OUT event. This selection lays dormant until the FORCE\_OUT signal transitions and then all outputs are

switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

[Figure 55-12](#) shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of [Figure 55-12](#) are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE\_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

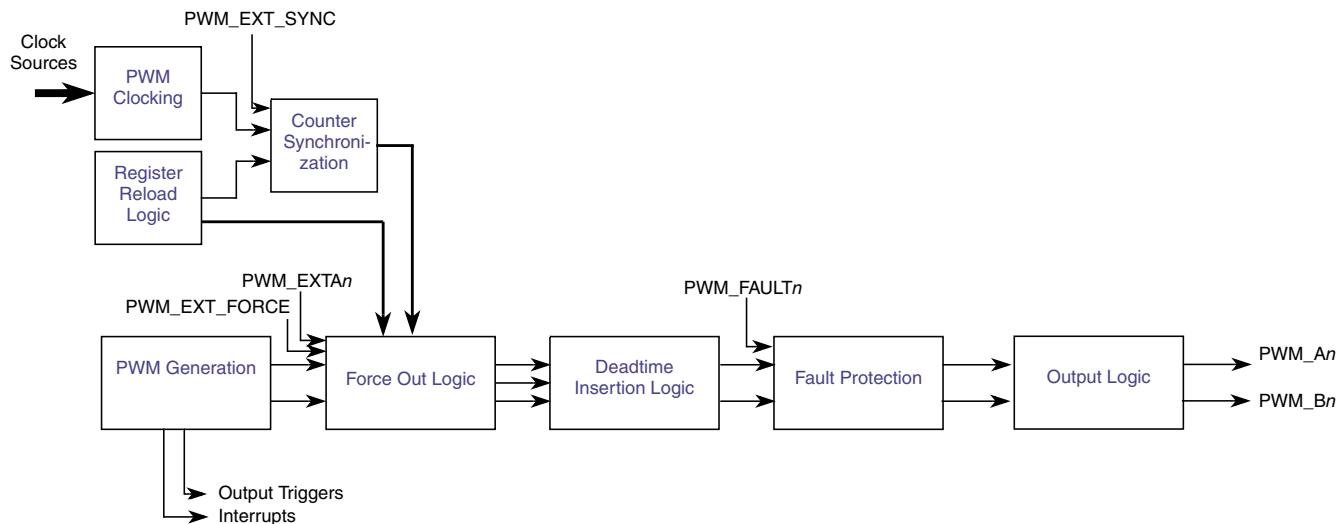

**Figure 55-12. Sensorless BLDC Commutation Using the Force Out Function**

### 55.3.2 Functional Details

This section describes the implementation of various sections of the PWM in greater detail.

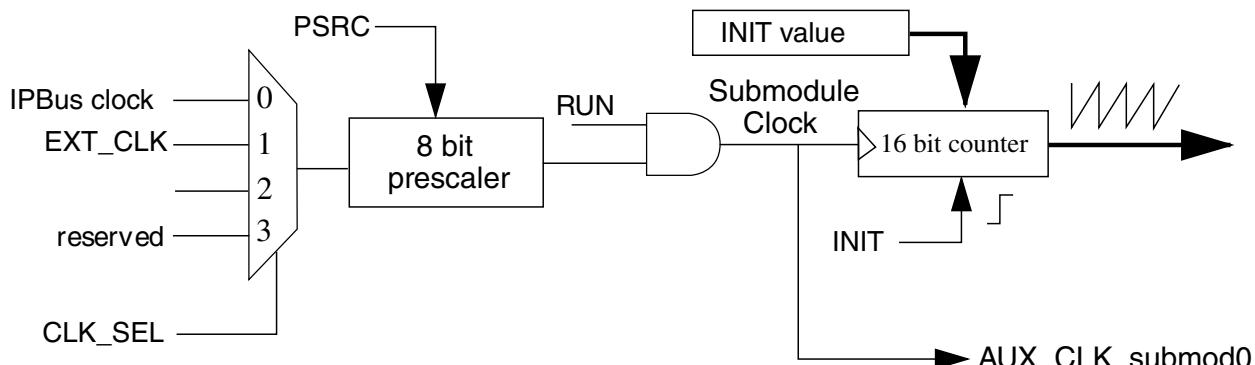

The following figure is a high-level block diagram of output PWM generation.

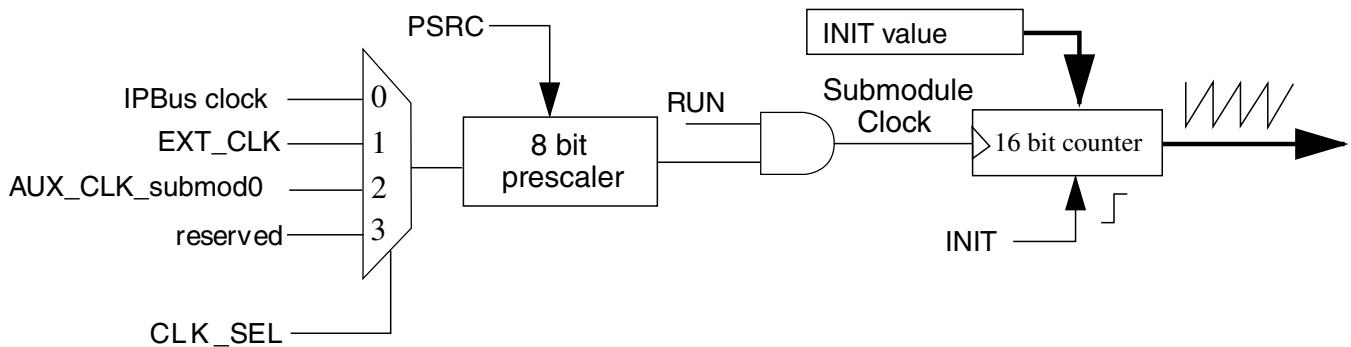

**Figure 55-13. High-Level Output PWM Generation Block Diagram**

### 55.3.2.1 PWM Clocking

Figure 55-14 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT\_CLK, and AUX\_CLK. The EXT\_CLK goes to all of the submodules. The AUX\_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8-bit prescaler and MCTRL[RUN] from submodule0 can control all of the submodules.

**Figure 55-14. Clocking Block Diagram for PWM Submodule 0**

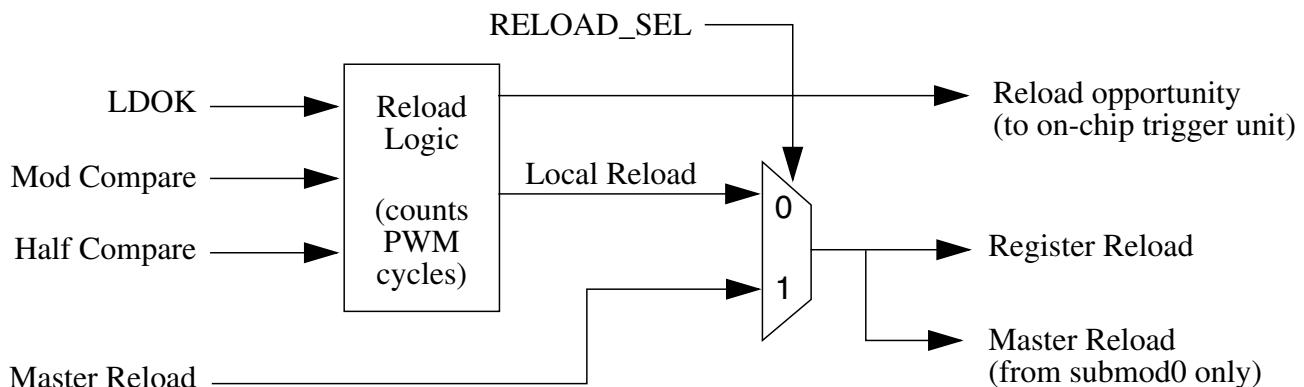

**Figure 55-15. Clocking Block Diagram for PWM Submodule 1,2,3**

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.

### 55.3.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL]. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

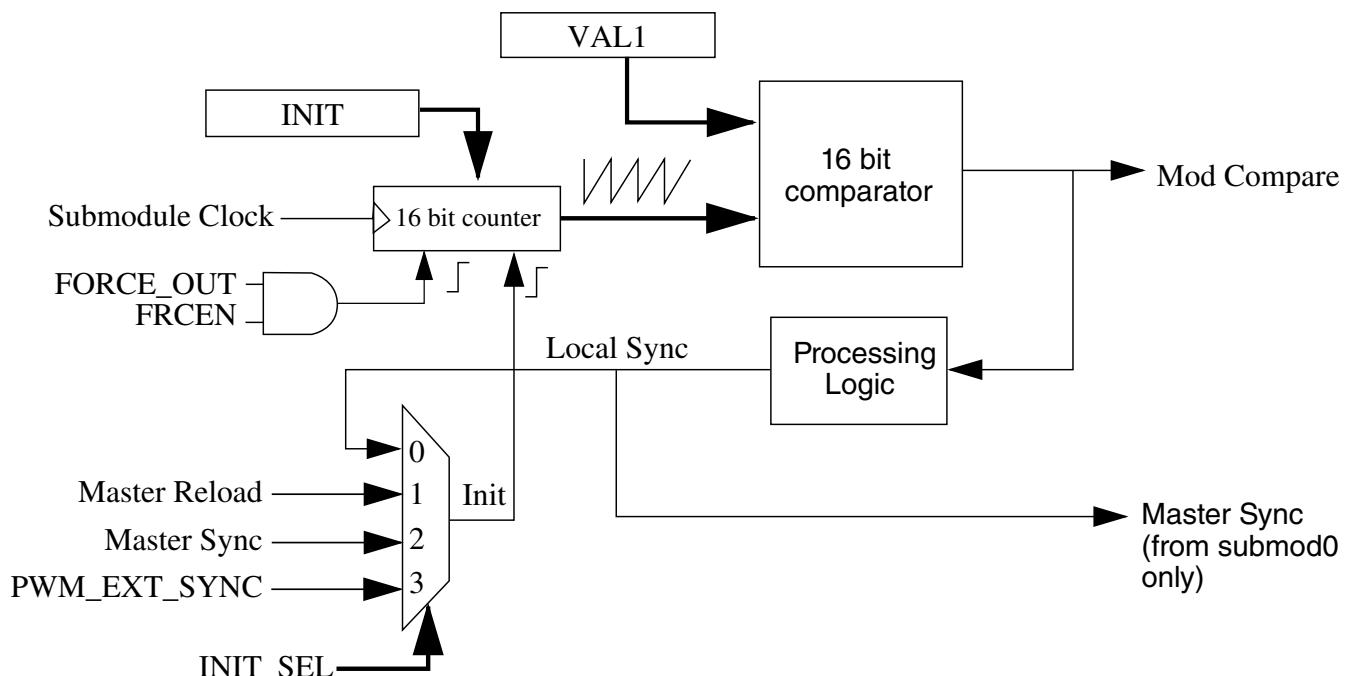

As illustrated in [Figure 55-16](#) the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

**Figure 55-16. Register Reload Logic**

### 55.3.2.3 Counter Synchronization

In the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

**Figure 55-17. Submodule Timer Synchronization**

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM\_EXT\_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period.

As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE\_OUT signal assuming that CTRL2[FRCEN] is set. As indicated by the preceding figure, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. A forced initialization will also cause a register reload if MCTRL[LDOOK] is set. The FORCE\_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

#### **55.3.2.4 PWM Generation**

[Figure 55-18](#) illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

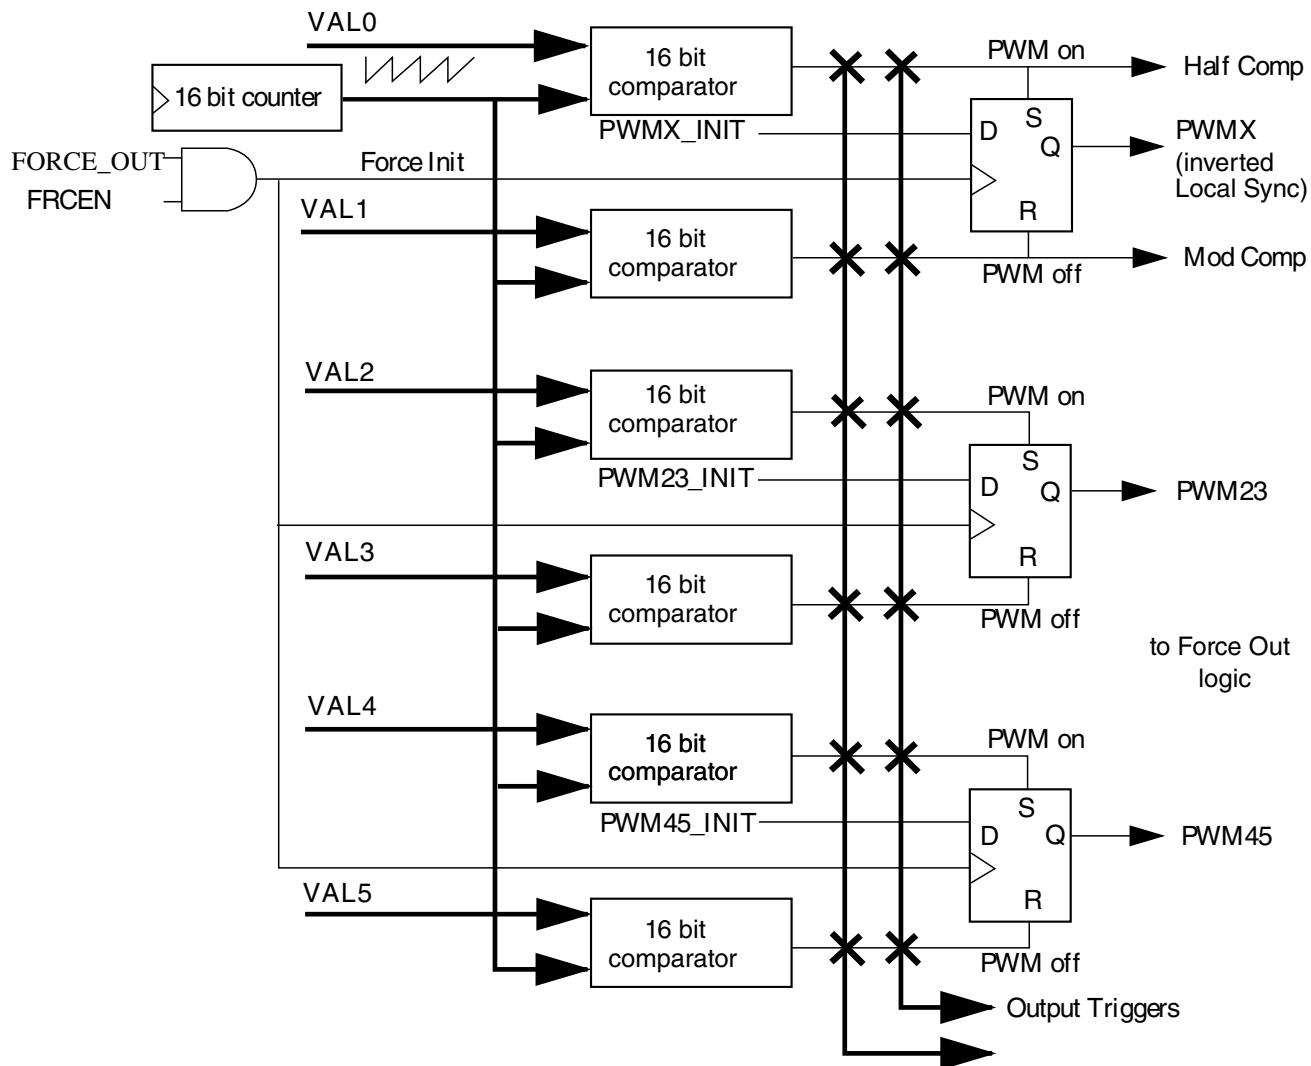

Figure 55-18. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Sync signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal, effectively turning it into an auxiliary PWM signal (PWM\_X) assuming that the PWM\_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in [Figure 55-18](#) are "equal to" comparators. In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

### **55.3.2.5 Output Compare Capabilities**

By using the VALx registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

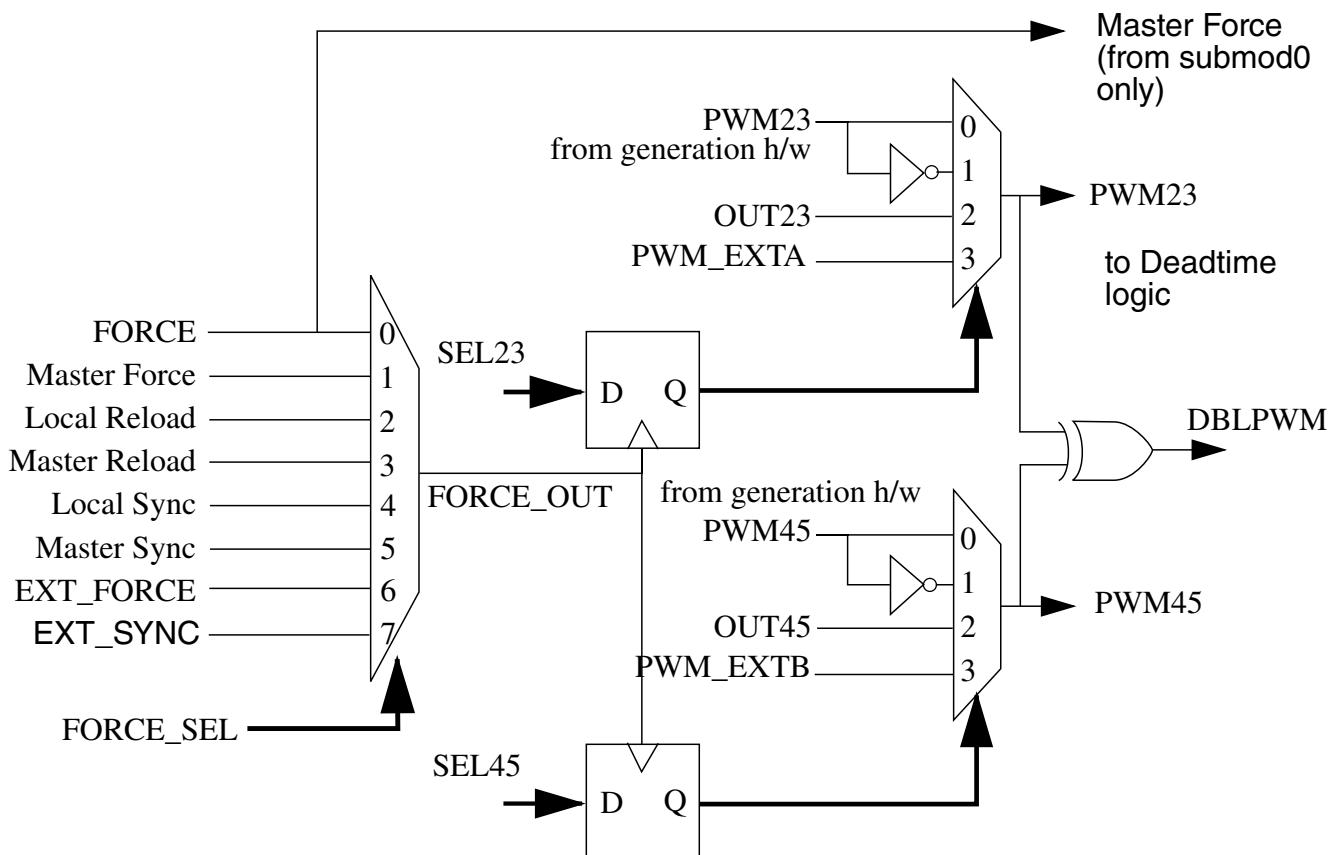

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM\_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWM\_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

### **55.3.2.6 Force Out Logic**

For each submodule, software can select between eight signal sources for the FORCE\_OUT signal: local CTRL2[FORCE], the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, the EXT\_SYNC signal from on- or off-chip, or the EXT\_FORCE signal from on- or off-chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output

pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT\_SYNC, or EXT\_FORCE signals should be selected.

Figure 55-19 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM\_EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE\_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.

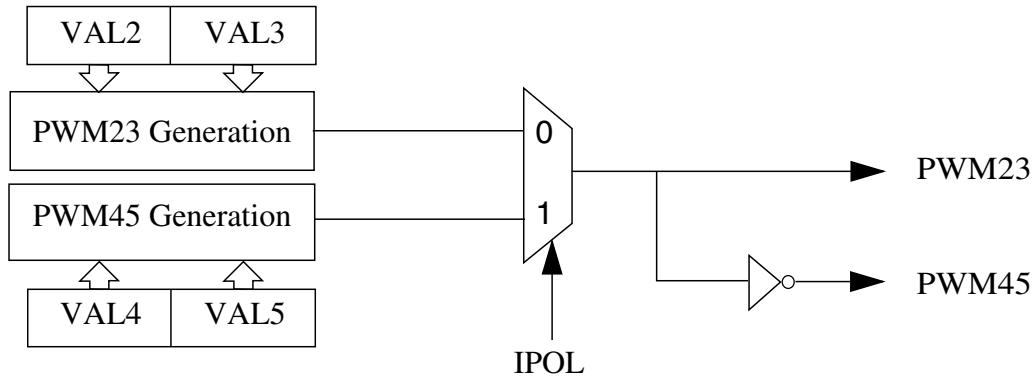

**Figure 55-19. Force Out Logic**

The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT\_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

### 55.3.2.7 Independent or Complementary Channel Operation

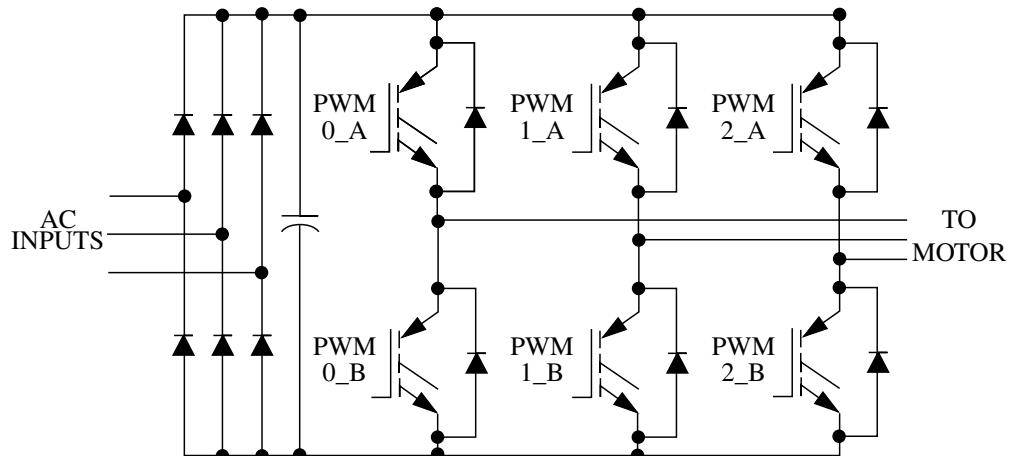

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in [Figure 55-20](#) in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by MCTRL[IPOL].

**Figure 55-20. Complementary Channel Pair**

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in [Figure 55-21](#).

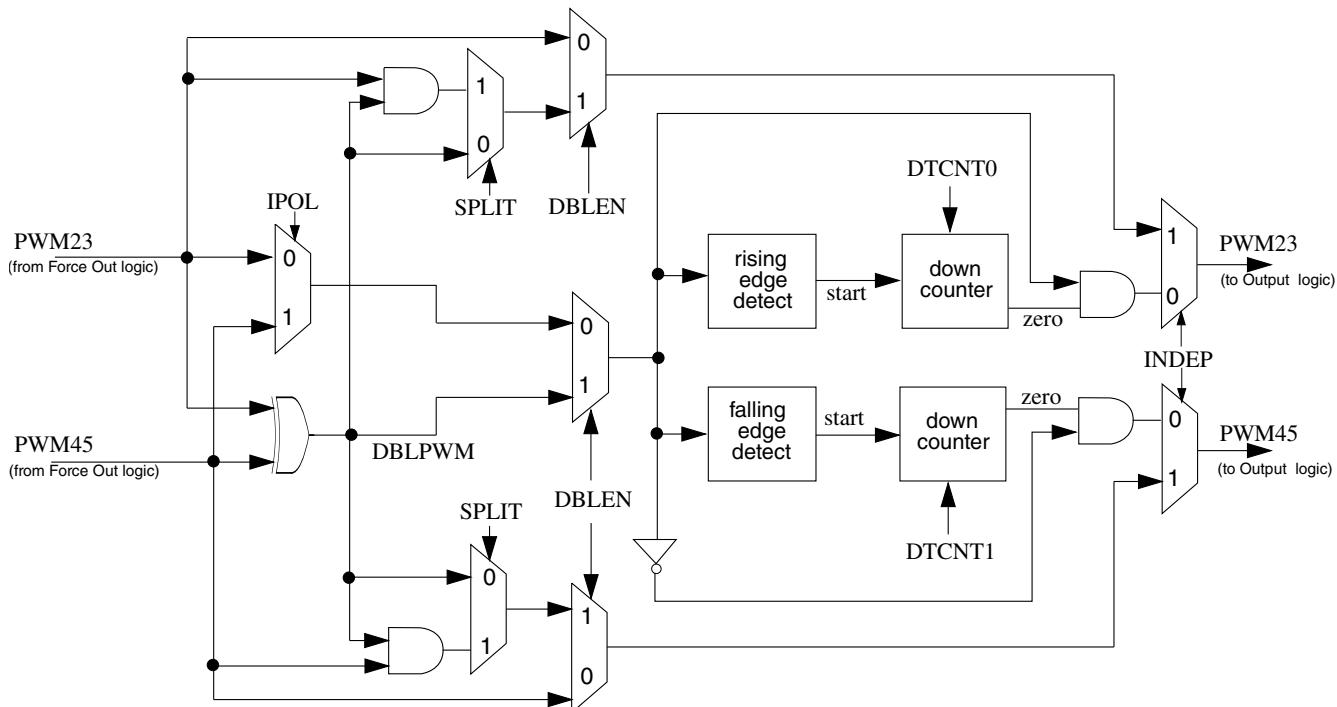

**Figure 55-21. Typical 3 Phase AC Motor Drive**

Complementary operation allows the use of the deadtime insertion feature.

### 55.3.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

**Figure 55-22. Deadtime Insertion Logic**

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

#### Note

To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. But the transistor's characteristics may make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

## Functional Description

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

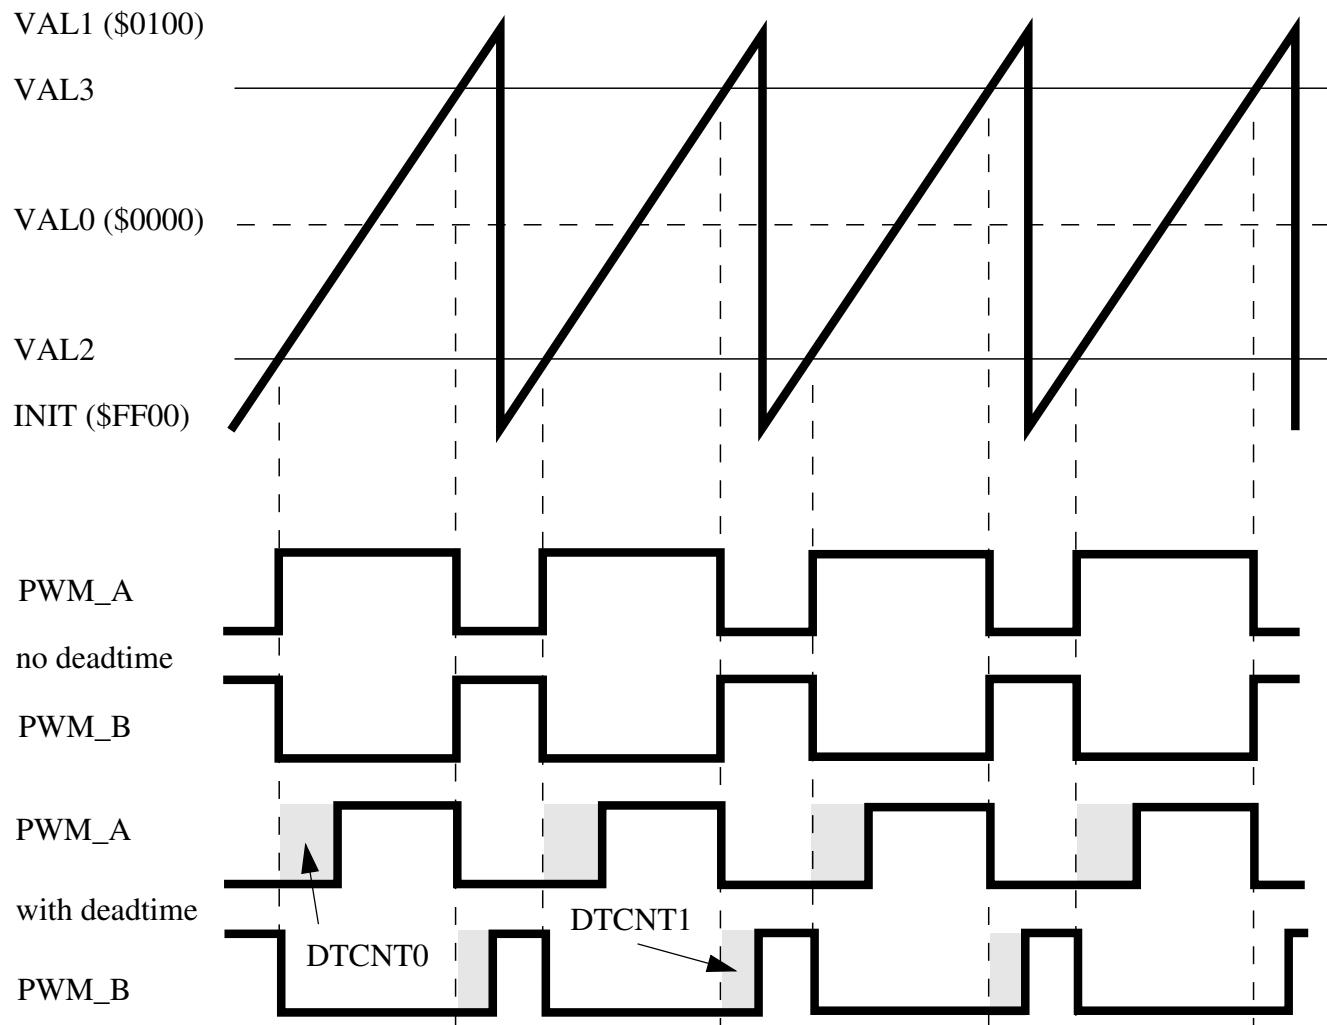

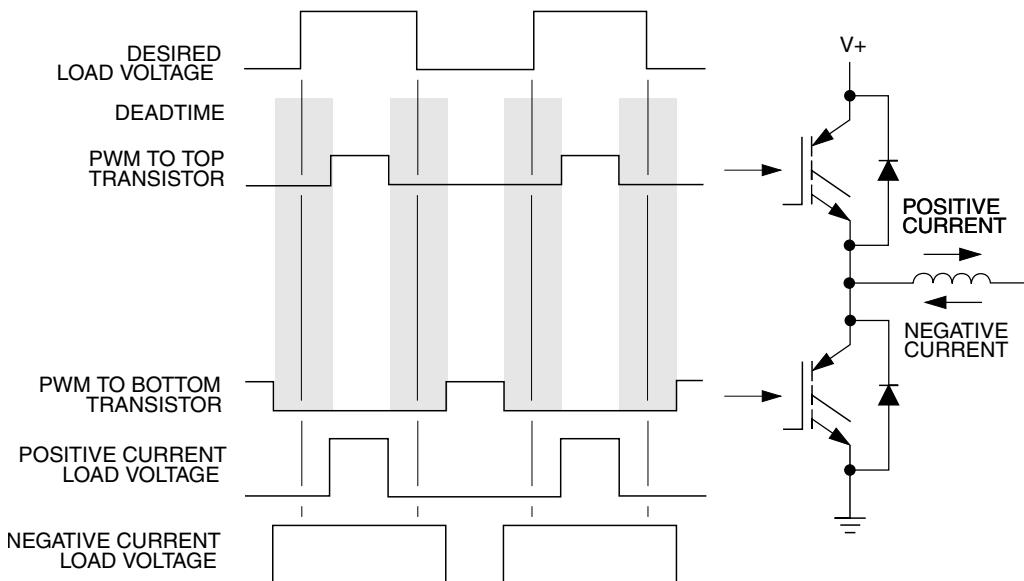

Figure 55-23. Deadtime Insertion

### 55.3.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

**Figure 55-24. Deadtime Distortion**

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform inverter outputs. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor inverter current for that pair, as the preceding figure shows. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWM<sub>X</sub>, for that driver
- The state of the odd/even correction bit, MCTRL[IPOL], for that driver

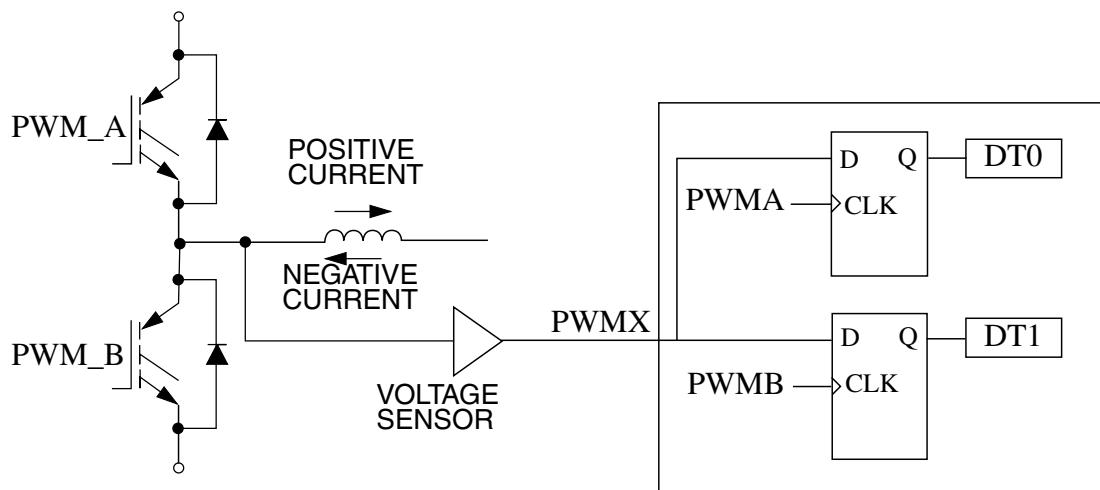

To correct deadtime distortion, software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

### 55.3.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker especially indicating when to toggle between PWM value registers.

Software can then set MCTRL[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

**Figure 55-25. Current-status Sense Scheme for Deadtime Correction**

Both D flip-flops latch low,  $\text{CTRL[DT]} = 00$ , during deadtime periods if current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high,  $\text{CTRL[DT]} = 11$ , during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. **Sampled results will be  $\text{CTRL[DT]} = \text{b}10$ . Thus, the best time to change one PWM value register to another is just before the current zero crossing.**

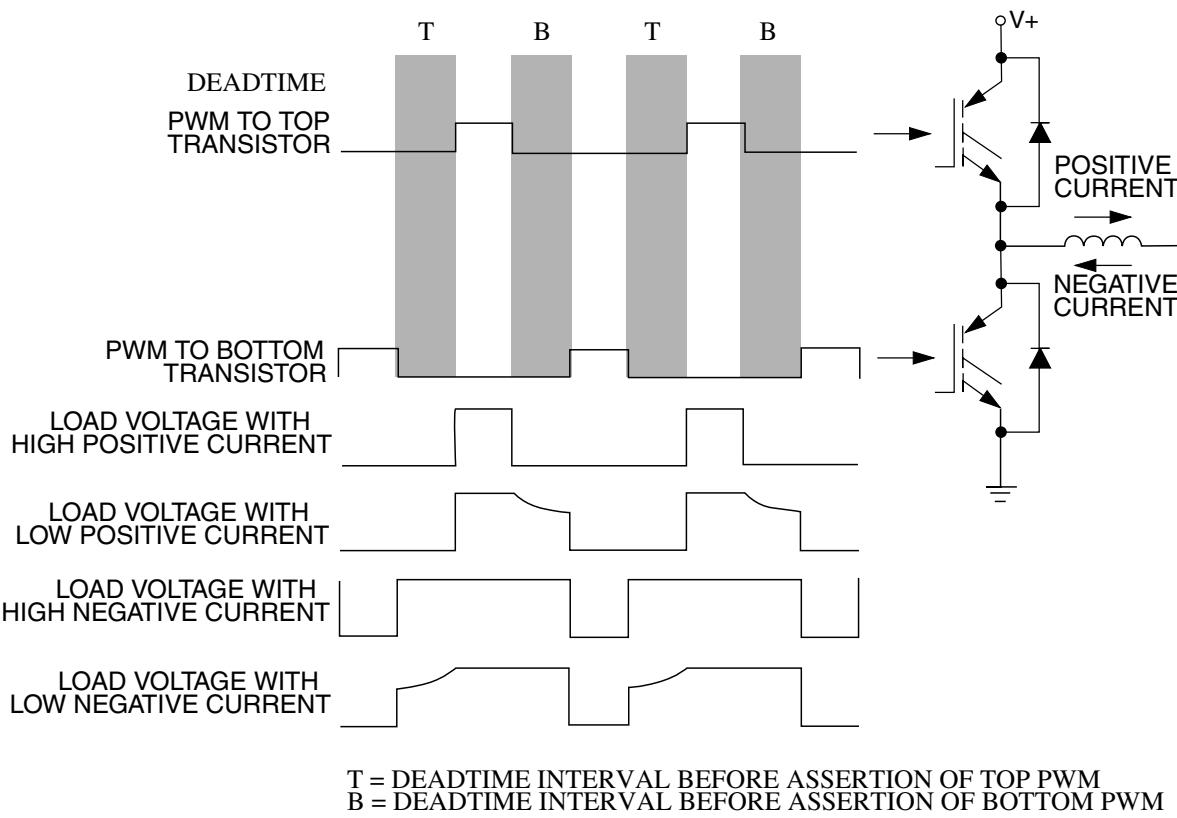

Figure 55-26. Output Voltage Waveforms

### 55.3.2.9 Fractional Delay Logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM\_A and PWM\_B outputs and fine resolution for the PWM period. Enable the use of the fractional delay logic by setting FRCTRL[FRACx\_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn on and turn off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFF for unsigned usage or 0x7FFE for signed usage. This limit is needed in order to avoid counter rollovers when accumulating the fractional additional period.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog NanoEdge placer block available.

### 55.3.2.9.1 Fractional Delay Logic with NanoEdge Placement Block

Using the NanoEdge placer block requires that the IPBus clock to the PWM be set at a defined frequency. The NanoEdge placer is powered up by setting FRCTRL[FRAC\_PU]. Enable fine edge control on the various PWM edges by setting FRCTRL[FRACx\_EN]. The fractional values in the FRACVALx registers allow placing the PWM edge or PWM period to a granularity of 1/32 of the IPBus clock period. For example, if you desire the rising edge of the PWMA output to occur at a count of 12.25, then program VAL2 with 0x000C and FRACVAL2 with 0x4000. Using FRACVAL1 will adjust the PWM period with the same granularity of 1/32 of a clock period.

If the FRCTRL[FRAC\_PU] bits in all of the submodules are clear, then the NanoEdge placer is powered down, and alternate clock frequencies can be used without the NanoEdge placement feature.

### 55.3.2.10 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (refer to the figure) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the OCTRL[PWMxFS] fields.

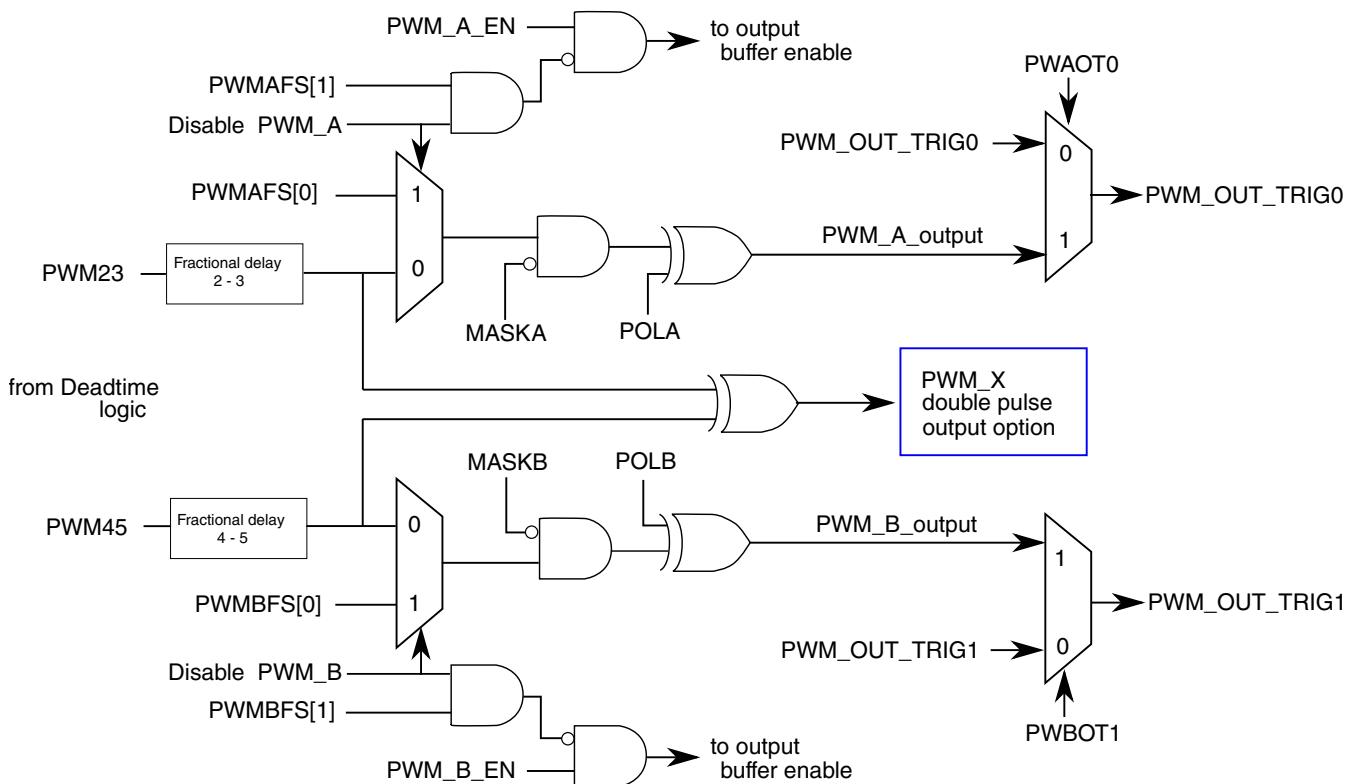

Figure 55-27. Output Logic

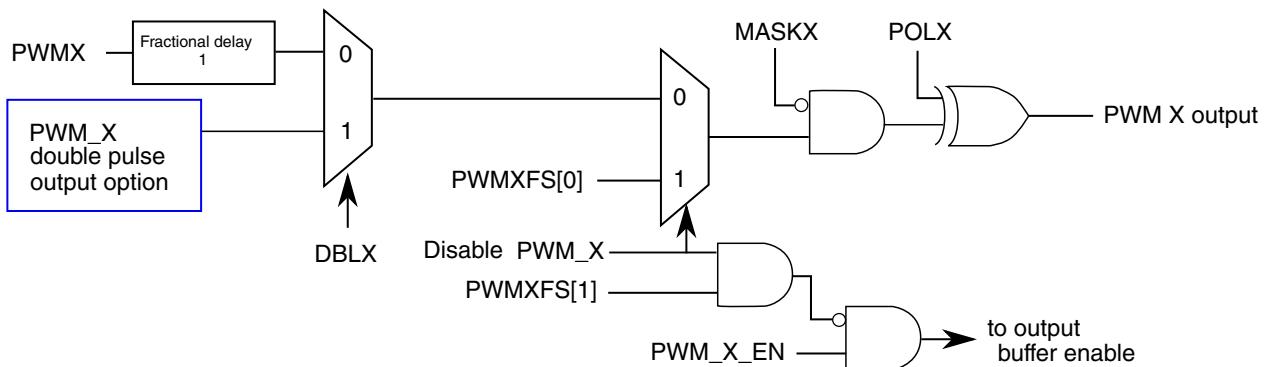

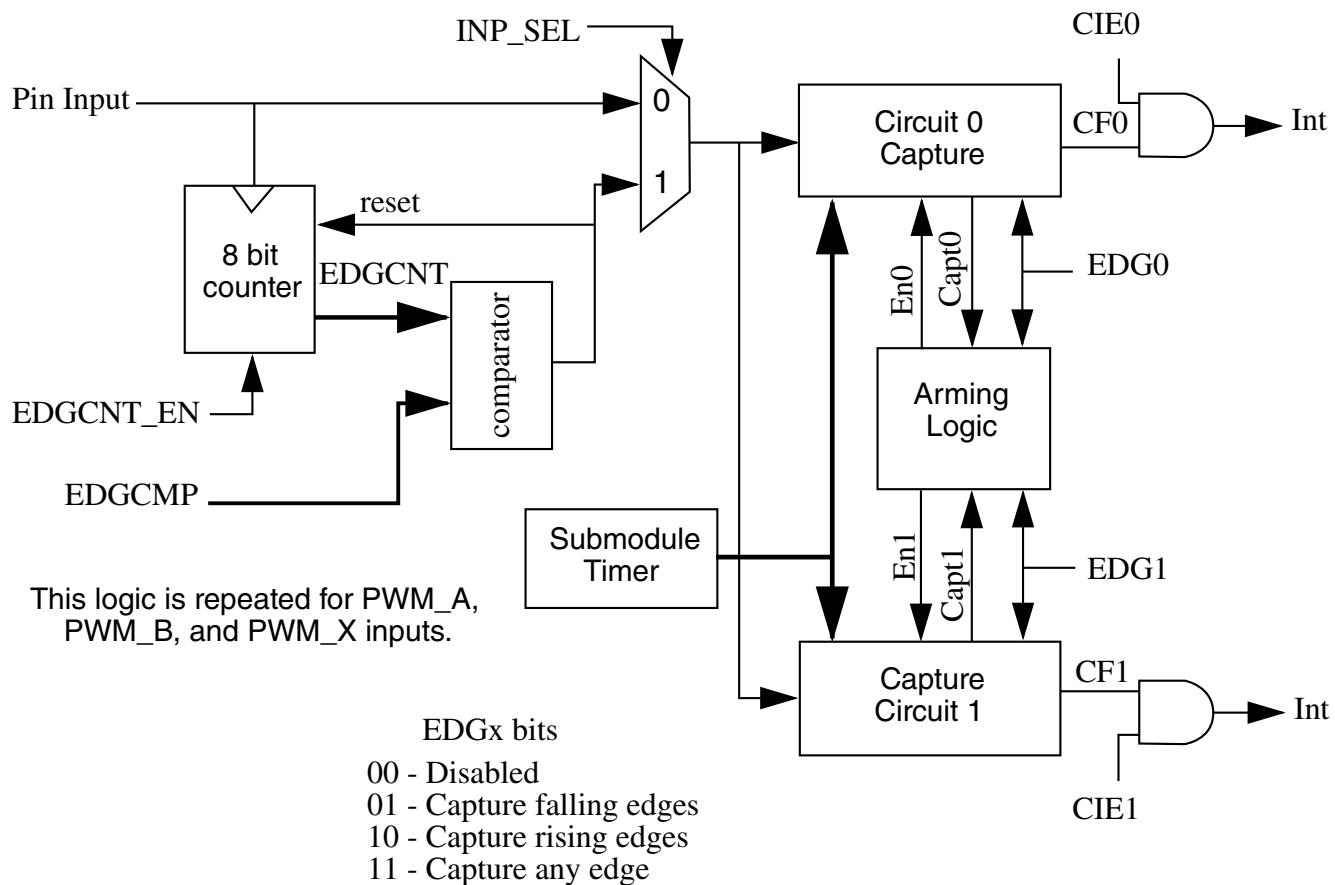

Figure 55-28. Output Logic continued

### 55.3.2.11 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

## Functional Description

The following figure is a block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8 bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8 bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this feature is useful for dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

**Figure 55-29. Enhanced Capture (E-Capture) Logic**

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by CAPTCTRL<sub>x</sub>[EDG<sub>x</sub>1] and CAPTCTRL<sub>x</sub>[EDG<sub>x</sub>0], whose functionality is listed in the preceding figure. Also, controlling the operation of the capture circuits is the arming

logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

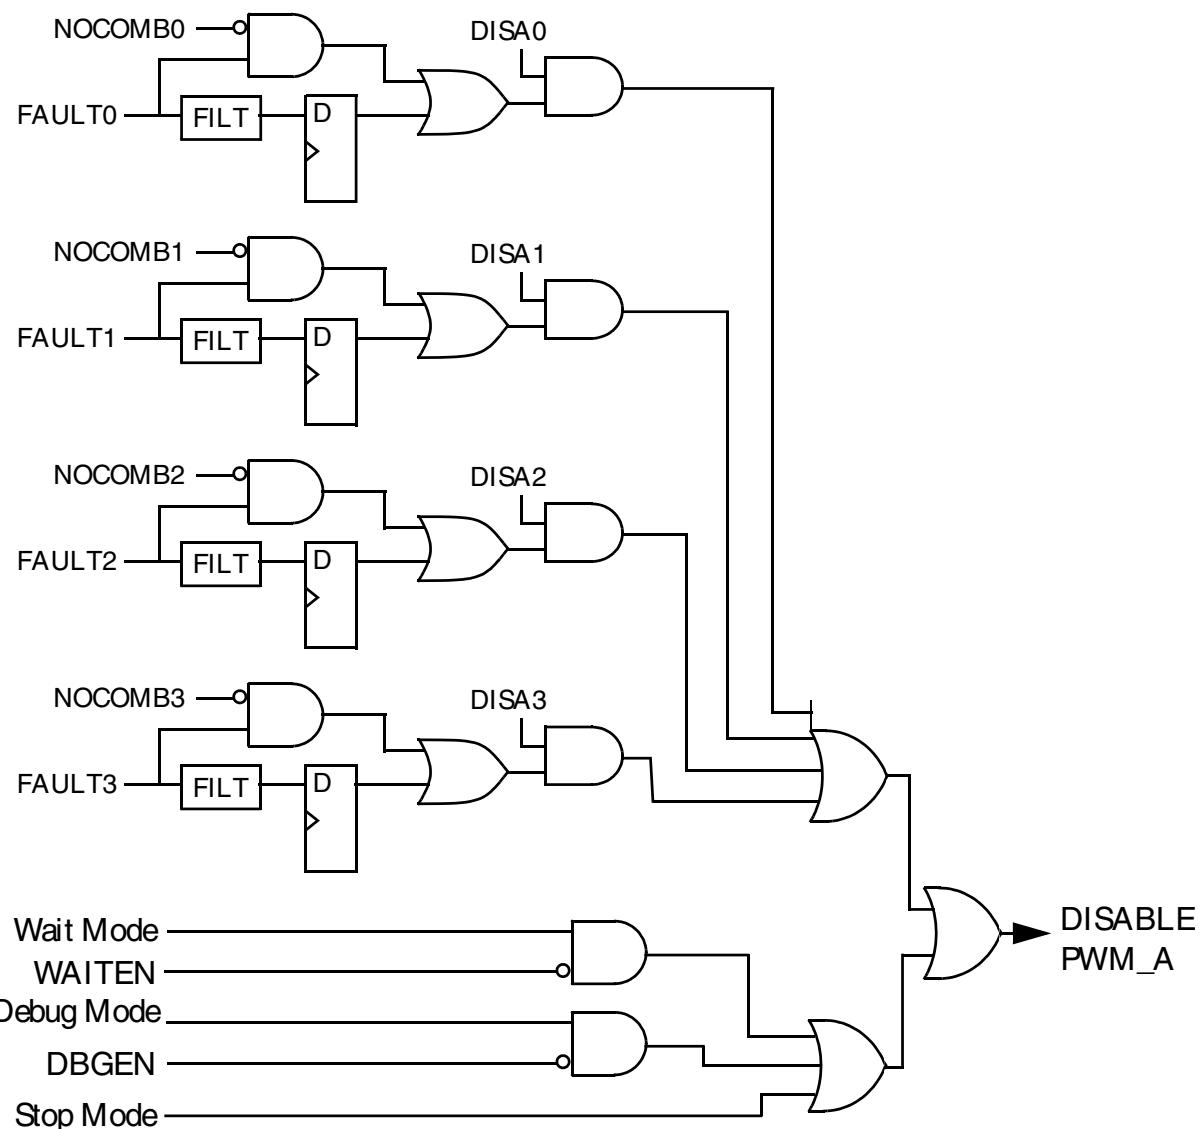

### 55.3.2.12 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

## Functional Description

**Figure 55-30. Fault Decoder for PWM\_A**

**Table 55-3. Fault Mapping**

PWM Pin	Controlling Register Bits
PWM_A	DISMAP0[DIS0A]
PWM_B	DISMAP0[DIS0B]
PWM_X	DISMAP0[DIS0X]

### 55.3.2.12.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with FFILT[FILT\_PER]. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using FFILT[FILT\_CNT]. Setting FFILT[FILT\_PER] to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FCTRL[FLVLx] is set), the corresponding FSTS[FFPINx] and fault flag, FSTS[FFLAGx], bits are set. FSTS[FFPINx] remains set as long as the filtered FAULTx pin is zero. Clear FSTS[FFLAGx] by writing a logic 1 to FSTS[FFLAGx].

If the FIEx, FAULTx pin interrupt enable bit is set, FSTS[FFLAGx] generates a CPU interrupt request. The interrupt request latch remains set until:

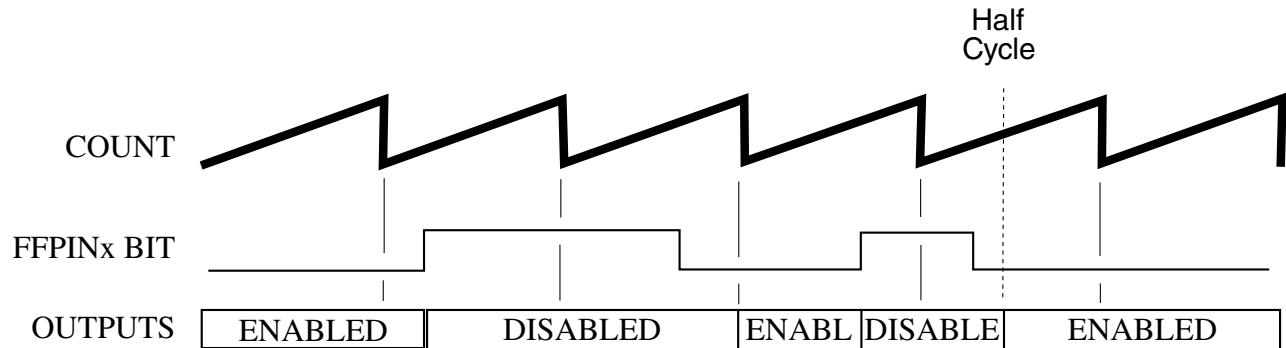

- Software clears FSTS[FFLAGx] by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

### 55.3.2.12.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for automatic clearing.

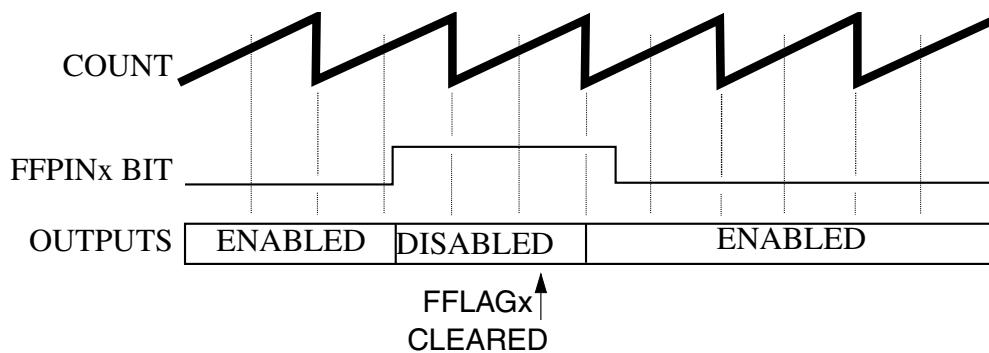

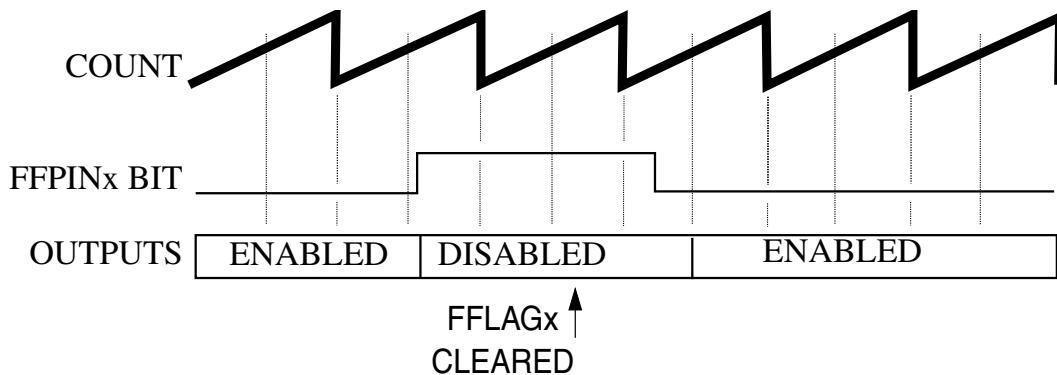

When FCTRL[FAUTOx] is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing FSTS[FFLAGx] does not affect disabled PWM pins when FCTRL[FAUTOx] is set.

**Figure 55-31. Automatic Fault Clearing**

### 55.3.2.12.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTTx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits, FCTRL[FSAFEx], are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the first following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.
- If the fault safety mode bits, FCTRL[FSAFEx], are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The filter detects a logic zero on the FAULTx pin at the start of the next PWM full or half cycle boundary. See the second following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

**Figure 55-32. Manual Fault Clearing (FCTRL[FSAFE]=0)****Figure 55-33. Manual Fault Clearing (FCTRL[FSAFE]=1)**

### Note

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM\_EXTA and PWM\_EXTB. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, MCTRL[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

#### 55.3.2.12.4 Fault Testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

### 55.3.3 PWM Generator Loading

### 55.3.3.1 Load Enable

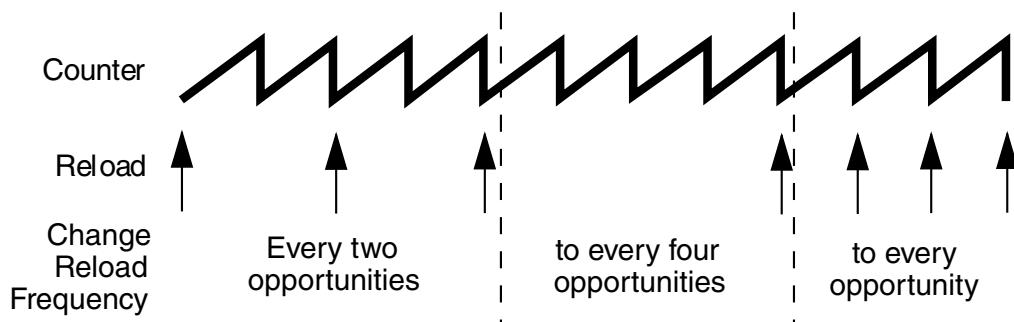

MCTRL[LDOOK] enables loading of the following PWM generator parameters:

- The prescaler divisor—from CTRL[PRSC]
- The PWM period and pulse width—from the INIT and VALx registers

MCTRL[LDOOK] allows software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL[LDOOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transferred to the inner set of registers immediately upon setting MCTRL[LDOOK] if CTRL[LDMOD] is set. Set MCTRL[LDOOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL[LDOOK] is automatically cleared.

### 55.3.3.2 Load Frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless the state of MCTRL[LDOOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

**Figure 55-34. Full Cycle Reload Frequency Change**

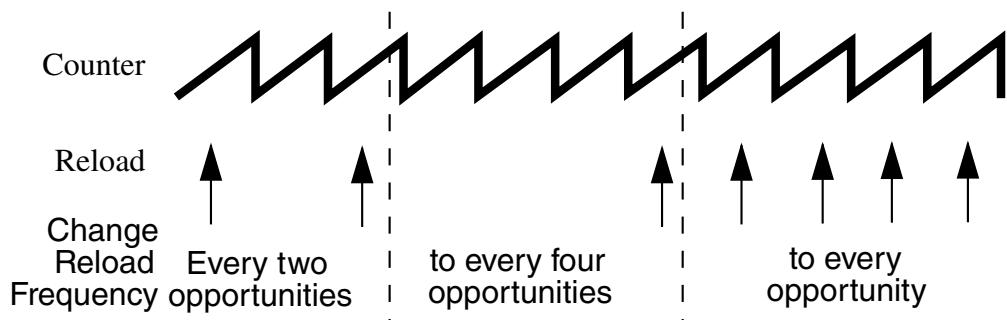

Figure 55-35. Half Cycle Reload Frequency Change

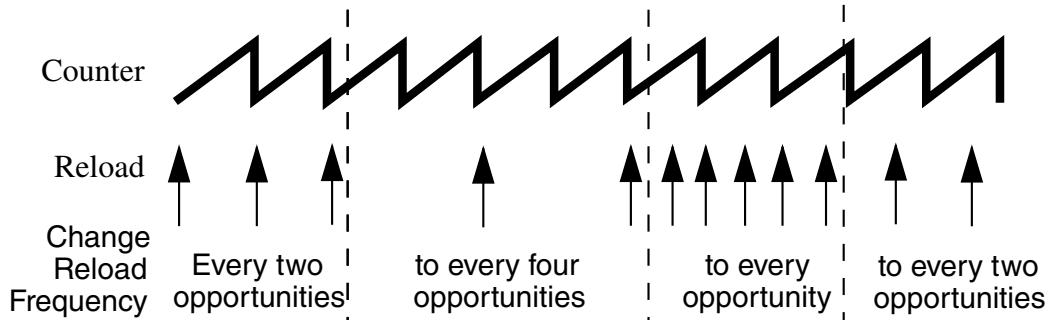

Figure 55-36. Full and Half Cycle Reload Frequency Change

### 55.3.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL[LDOCK]. If the PWM reload interrupt enable bit, INTEN[RIE], is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

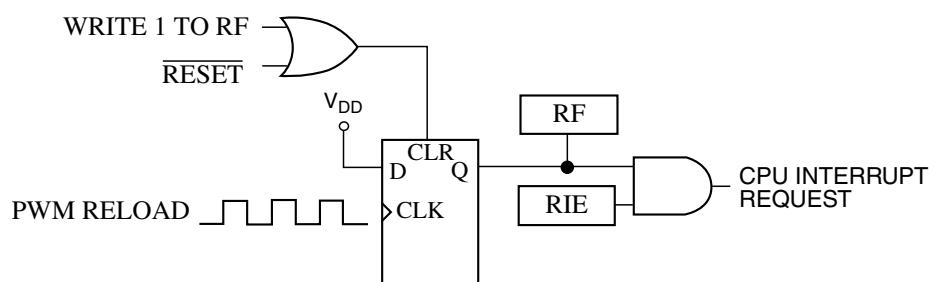

Figure 55-37. PWMF Reload Interrupt Request

### 55.3.3.4 Reload Errors

Whenever one of the VALx, FRACVALx, or CTRL[PRSC] registers is updated, the STS[RUF] flag is set to indicate that the data is not coherent. STS[RUF] will be cleared by a successful reload which consists of the reload signal while MCTRL[LDOK] is set. If STS[RUF] is set and MCTRL[LDOK] is clear when the reload signal occurs, a reload error has taken place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

### 55.3.3.5 Initialization

Initialize all registers and set MCTRL[LDOK] before setting MCTRL[RUN].

#### Note

Even if MCTRL[LDOK] is not set, setting MCTRL[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL[RUN].

The PWM generator uses the last values loaded if MCTRL[RUN] is cleared and then set while MCTRL[LDOK] equals zero.

When MCTRL[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

## 55.4 External Signals

The PWM has pins named PWM[n]\_A, PWM[n]\_B, PWM[n]\_X, FAULT[n], PWM[n]\_EXT\_SYNC, EXT\_FORCE, PWM[n]\_EXTA, and PWM[n]\_EXTB. The PWM also has an on-chip input called EXT\_CLK and an output signal called PWM[n]\_OUT\_TRIGx.

## 55.4.1 PWM[n]\_A and PWM[n]\_B - External PWM Output Pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

## 55.4.2 PWM[n]\_X - Auxiliary PWM Output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

X pins have limited usability as input capture - see note on pin 3103

## 55.4.3 FAULT[n] - Fault Inputs

These are input pins for disabling selected PWM outputs.

## 55.4.4 PWM[n]\_EXT\_SYNC - External Synchronization Signal

These input signals allow a source external to the PWM to initialize the PWM counter. In this manner, the PWM can be synchronized to external circuitry.

## 55.4.5 EXT\_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner, the PWM can be synchronized to external circuitry.

## 55.4.6 PWM[n]\_EXTA and PWM[n]\_EXTB - Alternate PWM Control Signals

These pins allow an alternate source to control the PWM\_A and PWM\_B outputs. Typically, either the PWM\_EXT\_A or PWM\_EXT\_B input (depending on the state of MCTRL[IPOL]) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

### 55.4.7 PWM[n].OUT\_TRIG0 and PWM[n].OUT\_TRIG1 - Output Triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the OUT\_TRIG\_EN bits in the Output Trigger Control Register for information about how to enable these outputs and how the compare registers match up to the output triggers.

### 55.4.8 EXT\_CLK - External Clock Signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. In this manner, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

## 55.5 Resets

All PWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tri-states the PWM outputs.

## 55.6 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

**Table 55-4. Interrupt Summary**

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMPO	SM0STS[CMPIF]	SM0INTEN[CMPIE]	Submodule 0 compare interrupt	Compare event has occurred
PWM_CAP0	SM0STS[CFA1], SM0STS[CFA0], SM0STS[CFB1], SM0STS[CFB0], SM0STS[CFX1],	SM0INTEN[CFA1IE], SM0INTEN[CFA0IE], SM0INTEN[CFB1IE], SM0INTEN[CFB0IE], SM0INTEN[CFX1IE],	Submodule 0 input capture interrupt	Input capture event has occurred

*Table continues on the next page...*

**Table 55-4. Interrupt Summary (continued)**

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
	SM0STS[CFX0]	SM0INTEN[CFX0IE]		
PWM_RELOAD0	SM0STS[RF]	SM0INTEN[RIE]	Submodule 0 reload interrupt	Reload event has occurred
PWM_CMP1	SM1STS[CMPF]	SM1INTEN[CMPIE]	Submodule 1 compare interrupt	Compare event has occurred
PWM_CAP1	SM1STS[CFA1], SM1STS[CFA0], SM1STS[CFB1], SM1STS[CFB0], SM1STS[CFX1], SM1STS[CFX0]	SM1INTEN[CFA1IE], SM1INTEN[CFA0IE], SM1INTEN[CFB1IE], SM1INTEN[CFB0IE], SM1INTEN[CFX1IE], SM1INTEN[CFX0IE]	Submodule 1 input capture interrupt	Input capture event has occurred
PWM_RELOAD1	SM1STS[RF]	SM1INTEN[RIE]	Submodule 1 reload interrupt	Reload event has occurred
PWM_CMP2	SM2STS[CMPF]	SM2INTEN[CMPIE]	Submodule 2 compare interrupt	Compare event has occurred
PWM_CAP2	SM2STS[CFA1], SM2STS[CFA0], SM2STS[CFB1], SM2STS[CFB0], SM2STS[CFX1], SM2STS[CFX0]	SM2INTEN[CFA1IE], SM2INTEN[CFA0IE], SM2INTEN[CFB1IE], SM2INTEN[CFB0IE], SM2INTEN[CFX1IE], SM2INTEN[CFX0IE]	Submodule 2 input capture interrupt	Input capture event has occurred
PWM_RELOAD2	SM2STS[RF]	SM2INTEN[RIE]	Submodule 2 reload interrupt	Reload event has occurred

## 55.7 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered VALx registers.

**Table 55-5. DMA Summary**

DMA Request	DMA Enable	Name	Description
Submodule 0 read request	SM0DMAEN[CX0DE]	SM0 Capture FIFO X0 read request	SM0CVAL0 contains a value to be read
	SM0DMAEN[CX1DE]	SM0 Capture FIFO X1 read request	SM0CVAL1 contains a value to be read
	SM0DMAEN[CA0DE]	SM0 Capture FIFO A0 read request	SM0CVAL2 contains a value to be read
	SM0DMAEN[CA1DE]	SM0 Capture FIFO A1 read request	SM0CVAL3 contains a value to be read
	SM0DMAEN[CB0DE]	SM0 Capture FIFO B0 read request	SM0CVAL4 contains a value to be read
	SM0DMAEN[CB1DE]	SM0 Capture FIFO B1 read request	SM0CVAL5 contains a value to be read
	SM0DMAEN[CAPTDE]	SM0 Capture FIFO read request source select	Selects source of submodule0 read DMA request
Submodule 0 write request	SM0DMAEN[VALDE]	SM0VALx write request	SM0VALx registers need to be updated
Submodule 1 read request	SM1DMAEN[CX0DE]	SM1 Capture FIFO X0 read request	SM1CVAL0 contains a value to be read
	SM1DMAEN[CX1DE]	SM1 Capture FIFO X1 read request	SM1CVAL1 contains a value to be read
	SM1DMAEN[CA0DE]	SM1 Capture FIFO A0 read request	SM1CVAL2 contains a value to be read
	SM1DMAEN[CA1DE]	SM1 Capture FIFO A1 read request	SM1CVAL3 contains a value to be read
	SM1DMAEN[CB0DE]	SM1 Capture FIFO B0 read request	SM1CVAL4 contains a value to be read
	SM1DMAEN[CB1DE]	SM1 Capture FIFO B1 read request	SM1CVAL5 contains a value to be read
	SM1DMAEN[CAPTDE]	SM1 Capture FIFO read request source select	Selects source of submodule1 read DMA request

Table continues on the next page...

**Table 55-5. DMA Summary (continued)**

DMA Request	DMA Enable	Name	Description
Submodule 1 write request	SM1DMAEN[VALDE]	SM1VALx write request	SM1VALx registers need to be updated
Submodule 2 read request	SM2DMAEN[CX0DE]	SM2 Capture FIFO X0 read request	SM2CVAL0 contains a value to be read
	SM2DMAEN[CX1DE]	SM2 Capture FIFO X! read request	SM2CVAL1 contains a value to be read
	SM2DMAEN[CA0DE]	SM2 Capture FIFO A0 read request	SM2CVAL2 contains a value to be read
	SM2DMAEN[CA1DE]	SM2 Capture FIFO A1 read request	SM2CVAL3 contains a value to be read
	SM2DMAEN[CB0DE]	SM2 Capture FIFO B0 read request	SM2CVAL4 contains a value to be read
	SM2DMAEN[CB1DE]	SM2 Capture FIFO B1 read request	SM2CVAL5 contains a value to be read
	SM2DMAEN[CAPTDE]	SM2 Capture FIFO read request source select	Selects source of submodule2 read DMA request
Submodule 2 write request	SM2DMAEN[VALDE]	SM2VALx write request	SM2VALx registers need to be updated
Submodule 3 read request	SM3DMAEN[CX0DE]	SM3 Capture FIFO X0 read request	SM3CVAL0 contains a value to be read
	SM3DMAEN[CX1DE]	SM3 Capture FIFO X! read request	SM3CVAL1 contains a value to be read
	SM3DMAEN[CA0DE]	SM3 Capture FIFO A0 read request	SM3CVAL2 contains a value to be read
	SM3DMAEN[CA1DE]	SM3 Capture FIFO A1 read request	SM3CVAL3 contains a value to be read
	SM3DMAEN[CB0DE]	SM3 Capture FIFO B0 read request	SM3CVAL4 contains a value to be read
	SM3DMAEN[CB1DE]	SM3 Capture FIFO B1 read request	SM3CVAL5 contains a value to be read
	SM3DMAEN[CAPTDE]	SM3 Capture FIFO read request source select	Selects source of submodule3 read DMA request
Submodule 3 write request	SM3DMAEN[VALDE]	SM3VALx write request	SM3VALx registers need to be updated

## 55.8 PWM register descriptions

## PWM register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The PWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel.

### NOTE

While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers, if the pairs are word-aligned.

Submodule registers are repeated for each PWM submodule. To designate which submodule they are in, register names are prefixed with SM<sub>x</sub>(x=0,1,2,3). The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is offset 0x60 from the base address for the PWM module as a whole. This 0x60 offset is based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same 0x60 offset. The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the PWM module as a whole plus an offset of 0x180.

Fault channel registers are repeated for each fault channel. To designate which fault channel they are in, register names are prefixed with F0 and F1. The base address of fault channel 0 is equal to the base address of the PWM module as a whole plus an offset of 0x18C. The base address of fault channel 1 is the base address of fault channel 0 + 0x4. This 0x4 offset is based on the number of registers in a fault channel. Each of the four fields in the fault channel registers corresponds to fault inputs 3-0.

### 55.8.1 PWM memory map

PWM1 base address: 403D\_C000h

PWM2 base address: 403E\_0000h

PWM3 base address: 403E\_4000h

PWM4 base address: 403E\_8000h

## 55.8.3 Initial Count Register (SM0INIT - SM3INIT)

### 55.8.3.1 Offset

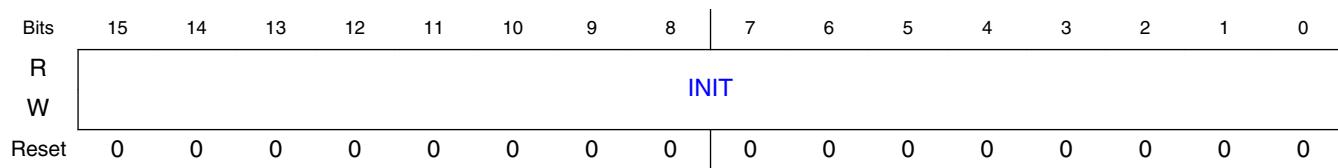

Register	Offset
SM0INIT	2h
SM1INIT	62h
SM2INIT	C2h
SM3INIT	122h

### 55.8.3.2 Function

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT\_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

**NOTE**

The INIT register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## 55.8.4.3 Fields

Field	Function
15 DBGEN	Debug Enable When set to one, the PWM will continue to run while the chip is in debug mode. If the device enters debug mode and this bit is zero, then the PWM outputs will be disabled until debug mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers.
14 WAITEN	WAIT Enable When set to one, the PWM will continue to run while the chip is in WAIT mode. In this mode, the peripheral clock continues to run but the CPU clock does not. If the device enters WAIT mode and this bit is zero, then the PWM outputs will be disabled until WAIT mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers.
13 INDEP	Independent or Complementary Pair Operation This bit determines if the PWM_A and PWM_B channels will be independent PWMs or a complementary PWM pair. 0b - PWM_A and PWM_B form a complementary PWM pair. 1b - PWM_A and PWM_B outputs are independent PWMs.
12 PWM23_INIT	PWM23 Initial Value This read/write bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT is asserted.
11 PWM45_INIT	PWM45 Initial Value This read/write bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT is asserted.
10 PWMX_INIT	PWM_X Initial Value This read/write bit determines the initial value for PWM_X and the value to which it is forced when FORCE_INIT is asserted.
9-8 INIT_SEL	Initialization Control Select These read/write bits control the source of the INIT signal which goes to the counter. 00b - Local sync (PWM_X) causes initialization. 01b - Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. The submodule counter will only reinitialize when a master reload occurs. 10b - Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0.

Table continues on the next page...

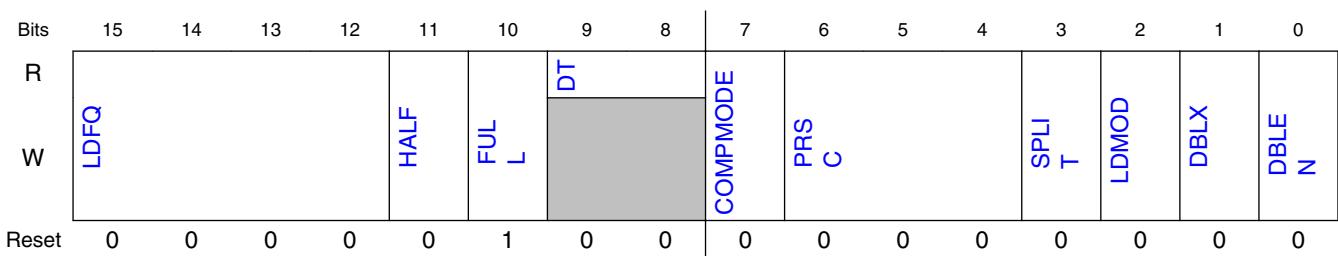

Field	Function
	11b - EXT_SYNC causes initialization.
7 FRCEN	FRCEN This bit allows the CTRL2[FORCE] signal to initialize the counter without regard to the signal selected by CTRL2[INIT_SEL]. This is a software controlled initialization. A forced initialization will also assert the register reload if MCTRL[LDOCK] is set. 0b - Initialization from a FORCE_OUT is disabled. 1b - Initialization from a FORCE_OUT is enabled.
6 FORCE	Force Initialization If CTRL2[FORCE_SEL] is set to 000, writing a 1 to this bit results in a FORCE_OUT event. This causes the following actions to be taken: <ul style="list-style-type: none"><li>• The PWM_A and PWM_B output pins will assume values based on DTSRCSEL[SMxSEL23] and DTSRCSEL[SMxSEL45].</li><li>• If CTRL2[FRCEN] is set, the counter value will be initialized with the INIT register value.</li></ul>
5-3 FORCE_SEL	This read/write bit determines the source of the FORCE OUTPUT signal for this submodule. 000b - The local force signal, CTRL2[FORCE], from this submodule is used to force updates. 001b - The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0. 010b - The local reload signal from this submodule is used to force updates without regard to the state of LDOCK. 011b - The master reload signal from submodule 0 is used to force updates if LDOCK is set. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0. 100b - The local sync signal from this submodule is used to force updates. 101b - The master sync signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0. 110b - The external force signal, EXT_FORCE, from outside the PWM module causes updates. 111b - The external sync signal, EXT_SYNC, from outside the PWM module causes updates.
2 RELOAD_SEL	Reload Source Select This read/write bit determines the source of the RELOAD signal for this submodule. When this bit is set, MCTRL[LDOCK[0]] for submodule 0 should be used since the local MCTRL[LDOCK] will be ignored. 0b - The local RELOAD signal is used to reload registers. 1b - The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it will force the RELOAD signal to logic 0.
1-0 CLK_SEL	Clock Source Select These read/write bits determine the source of the clock signal for this submodule. 00b - The IPBus clock is used as the clock for the local prescaler and counter. 01b - EXT_CLK is used as the clock for the local prescaler and counter. 10b - Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it will force the clock to logic 0. 11b - reserved

## 55.8.5 Control Register (SM0CTRL - SM3CTRL)

### 55.8.5.1 Offset

Register	Offset
SM0CTRL	6h
SM1CTRL	66h
SM2CTRL	C6h
SM3CTRL	126h

### 55.8.5.2 Diagram

### 55.8.5.3 Fields

Field	Function
15-12 LDFQ	<p>Load Frequency</p> <p>These buffered read/write bits select the PWM load frequency. Reset clears LDFQ, selecting loading every PWM opportunity. A PWM opportunity is determined by HALF and FULL.</p> <p><b>NOTE:</b> LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect.</p> <ul style="list-style-type: none"> <li>0000b - Every PWM opportunity</li> <li>0001b - Every 2 PWM opportunities</li> <li>0010b - Every 3 PWM opportunities</li> <li>0011b - Every 4 PWM opportunities</li> <li>0100b - Every 5 PWM opportunities</li> <li>0101b - Every 6 PWM opportunities</li> <li>0110b - Every 7 PWM opportunities</li> <li>0111b - Every 8 PWM opportunities</li> <li>1000b - Every 9 PWM opportunities</li> <li>1001b - Every 10 PWM opportunities</li> <li>1010b - Every 11 PWM opportunities</li> <li>1011b - Every 12 PWM opportunities</li> <li>1100b - Every 13 PWM opportunities</li> <li>1101b - Every 14 PWM opportunities</li> <li>1110b - Every 15 PWM opportunities</li> <li>1111b - Every 16 PWM opportunities</li> </ul>

Table continues on the next page...

Field	Function
11 HALF	<p>Half Cycle Reload</p> <p>This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be half way through the PWM cycle.</p> <p>0b - Half-cycle reloads disabled. 1b - Half-cycle reloads enabled.</p>
10 FULL	<p>Full Cycle Reload</p> <p>This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set in order to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle.</p> <p>0b - Full-cycle reloads disabled. 1b - Full-cycle reloads enabled.</p>
9-8 DT	<p>Deadtime</p> <p>These read only bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.</p>
7 COMPMODE	<p>Compare Mode</p> <p>This bit controls how comparisons are made between the VAL* registers and the PWM submodule counter. This bit can only be written one time after which it requires a reset to release the bit for writing again.</p> <p>0b - The VAL* registers and the PWM counter are compared using an "equal to" method. This means that PWM edges are only produced when the counter is equal to one of the VAL* register values. This implies that a PWMA output that is high at the end of a period will maintain this state until a match with VAL3 clears the output in the following period.</p> <p>1b - The VAL* registers and the PWM counter are compared using an "equal to or greater than" method. This means that PWM edges are produced when the counter is equal to or greater than one of the VAL* register values. This implies that a PWMA output that is high at the end of a period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.</p>
6-4 PRSC	<p>Prescaler</p> <p>These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL].</p> <p><b>NOTE:</b> Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit, MCTRL[LDOCK], is set or CTRL[LDMOD] is set. This field cannot be written when MCTRL[LDOCK] is set.</p> <p>000b - Prescaler 1. PWM clock frequency = <math>f_{clk}</math>      001b - Prescaler 2. PWM clock frequency = <math>f_{clk}/2</math>      010b - Prescaler 4. PWM clock frequency = <math>f_{clk}/4</math>      011b - Prescaler 8. PWM clock frequency = <math>f_{clk}/8</math>      100b - Prescaler 16. PWM clock frequency = <math>f_{clk}/16</math>      101b - Prescaler 32. PWM clock frequency = <math>f_{clk}/32</math>      110b - Prescaler 64. PWM clock frequency = <math>f_{clk}/64</math>      111b - Prescaler 128. PWM clock frequency = <math>f_{clk}/128</math></p>
3 SPLIT	<p>Split the DBLPWM signal to PWMA and PWMB</p> <p>This read/write bit is only used in independent mode when DBLEN is set. This bit allows the two PWM pulses generated by DBLEN to be split with one pulse on PWMA and one on PWMB. The two pulses within the same PWM period are created by an XOR function of the PWMA and PWMB sources. The</p>

Table continues on the next page...

## PWM register descriptions

Field	Function
	<p>splitting function causes PWMA to output the pulse that occurs when the PWMA source is 1 and the PWMB source is 0. The PWMB output occurs when the PWMB source is 1 and the PWMA source is 0. (See <a href="#">Double Switching PWMs</a>.)</p> <p>0b - DBLPWM is not split. PWMA and PWMB each have double pulses. 1b - DBLPWM is split to PWMA and PWMB.</p>
2 LDMOD	<p>Load Mode Select</p> <p>This read/write bit selects the timing of loading the buffered registers for this submodule.</p> <p>0b - Buffered registers of this submodule are loaded and take effect at the next PWM reload if MCTRL[LDOK] is set. 1b - Buffered registers of this submodule are loaded and take effect immediately upon MCTRL[LDOK] being set. In this case it is not necessary to set CTRL[FULL] or CTRL[HALF].</p>
1 DBLX	<p>PWMX Double Switching Enable</p> <p>This read/write bit enables the double switching behavior on PWMX. When this bit is set, the PWMX output shall be the exclusive OR combination of PWMA and PWMB prior to polarity and masking considerations.</p> <p>0b - PWMX double pulse disabled. 1b - PWMX double pulse enabled.</p>
0 DBLEN	<p>Double Switching Enable</p> <p>This read/write bit enables the double switching PWM behavior(See <a href="#">Double Switching PWMs</a>). Double switching is not compatible with fractional PWM clock generation. Make sure this bit is clear when setting FRCTRL[FRAC23_EN], FRCTRL[FRAC45_EN], or FRCTRL[FRAC1_EN].</p> <p>0b - Double switching disabled. 1b - Double switching enabled.</p>

## 55.8.6 Value Register 0 (SM0VAL0 - SM3VAL0)

### 55.8.6.1 Offset

Register	Offset
SM0VAL0	Ah
SM1VAL0	6Ah
SM2VAL0	CAh
SM3VAL0	12Ah

## 55.8.6.2 Diagram

Bits	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	VAL0	0	0	0	0	0	0	0	0
W	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

## 55.8.6.3 Fields

Field	Function
15-0 VAL0	<p>Value Register 0</p> <p>The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWM_X signal is set and the local sync signal is reset. This register is not byte accessible.</p> <p><b>NOTE:</b> The VAL0 register is buffered. The value written does not take effect until MCTRL[LDOCK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL0 cannot be written when MCTRL[LDOCK] is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.</p>

## 55.8.7 Fractional Value Register 1 (SM0FRACVAL1 - SM3FRACVAL1)

### 55.8.7.1 Offset

Register	Offset
SM0FRACVAL1	Ch
SM1FRACVAL1	6Ch
SM2FRACVAL1	CCh
SM3FRACVAL1	12Ch

## 55.8.7.2 Diagram

R													0				
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

## 55.8.7.3 Fields

Field	Function
15-11 FRACVAL1	<p>Fractional Value 1 Register</p> <p>These bits act as a fractional addition to the value in the VAL1 register which controls the PWM period width. The PWM period is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL1 is temporarily incremented and the PWM cycle is extended by one clock period to compensate for the accumulated fractional values.</p> <p><b>NOTE:</b> The FRACVAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL1 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.</p>
10-0 —	RESERVED

## 55.8.8 Value Register 1 (SM0VAL1 - SM3VAL1)

### 55.8.8.1 Offset

Register	Offset
SM0VAL1	Eh
SM1VAL1	6Eh
SM2VAL1	CEh
SM3VAL1	12Eh

### 55.8.8.2 Diagram

Bits	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	VAL1																
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

### 55.8.8.3 Fields

Field	Function
15-0 VAL1	<p>Value Register 1</p> <p>The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible.</p> <p><b>NOTE:</b> The VAL1 register is buffered. The value written does not take effect until MCTRL[LDOCK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL[LDOCK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.</p> <p><b>NOTE:</b> When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFF for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.</p> <p><b>NOTE:</b> If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. After the count reaches VAL1, the PWMX output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.</p>

## 55.8.9 Fractional Value Register 2 (SM0FRACVAL2 - SM3FRACVAL2)

### 55.8.9.1 Offset

Register	Offset
SM0FRACVAL2	10h
SM1FRACVAL2	70h
SM2FRACVAL2	D0h
SM3FRACVAL2	130h

### 55.8.9.2 Diagram

## 55.8.19.3 Fields

Field	Function
15	RESERVED
14 RUF	Registers Updated Flag  This read-only flag is set when one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers has been written, which indicates potentially non-coherent data in the set of double buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal while MCTRL[LDOK] = 1. Reset clears this bit.  0b - No register update has occurred since last reload. 1b - At least one of the double buffered registers has been updated since the last reload.
13 REF	Reload Error Flag  This read/write flag is set when a reload cycle occurs while MCTRL[LDOK] is 0 and the double buffered registers are in a non-coherent state (STS[RUF] = 1). Clear this bit by writing a logic one to this location. Reset clears this bit.  0b - No reload error occurred. 1b - Reload signal occurred with non-coherent data and MCTRL[LDOK] = 0.
12 RF	Reload Flag  This read/write flag is set at the beginning of every reload cycle regardless of the state of MCTRL[LDOK]. Clear this bit by writing a logic one to this location when DMAEN[VALDE] is clear (non-DMA mode). This flag can also be cleared by the DMA done signal when DMAEN[VALDE] is set (DMA mode) . Reset clears this bit.  0b - No new reload cycle since last STS[RF] clearing 1b - New reload cycle since last STS[RF] clearing
11 CFA1	Capture Flag A1  This bit is set when a capture event occurs on the Capture A1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA1DE] is set (DMA mode) . Reset clears this bit.
10 CFA0	Capture Flag A0  This bit is set when a capture event occurs on the Capture A0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA0DE] is set (DMA mode) . Reset clears this bit.
9 CFB1	Capture Flag B1

Table continues on the next page...

## PWM register descriptions

Field	Function
	This bit is set when a capture event occurs on the Capture B1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB1DE] is set (DMA mode) . Reset clears this bit.
8 CFB0	Capture Flag B0  This bit is set when a capture event occurs on the Capture B0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB0DE] is set (DMA mode) . Reset clears this bit.
7 CFX1	Capture Flag X1  This bit is set when a capture event occurs on the Capture X1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX1DE] is set (DMA mode) . Reset clears this bit.
6 CFX0	Capture Flag X0  This bit is set when a capture event occurs on the Capture X0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX0DE] is set (DMA mode) . Reset clears this bit.
5-0 CMPF	Compare Flags  These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position.  000000b - No compare event has occurred for a particular VALx value. 000001b - A compare event has occurred for a particular VALx value.

## 55.8.20 Interrupt Enable Register (SM0INTEN - SM3INTEN)

### 55.8.20.1 Offset

Register	Offset

7 CX1IE	<p>Capture X 1 Interrupt Enable</p> <p>This bit allows the STS[CFX1] flag to create an interrupt request to the CPU. Do not set both this bit and DMAEN[CX1DE].</p> <p>0b - Interrupt request disabled for STS[CFX1]. 1b - Interrupt request enabled for STS[CFX1].</p>
6 CX0IE	<p>Capture X 0 Interrupt Enable</p> <p>This bit allows the STS[CFX0] flag to create an interrupt request to the CPU. Do not set both this bit and DMAEN[CX0DE].</p>

*Table continues on the next page...*

## PWM register descriptions

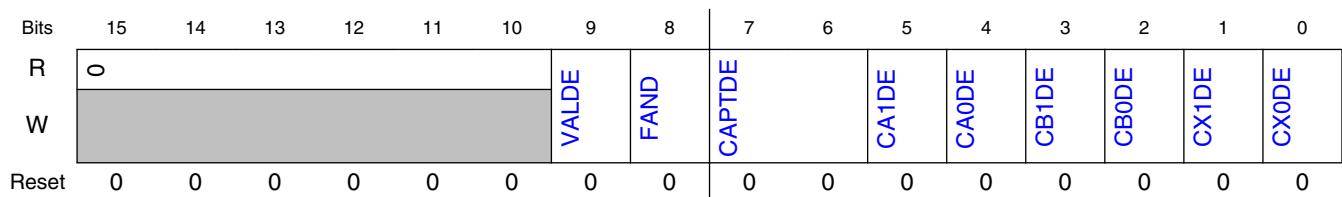

Field	Function
	0b - Interrupt request disabled for STS[CFX0]. 1b - Interrupt request enabled for STS[CFX0].
5-0 CMPIE	Compare Interrupt Enables  These bits enable the STS[CMPIF] flags to cause a compare interrupt request to the CPU.  000000b - The corresponding STS[CMPIF] bit will not cause an interrupt request. 000001b - The corresponding STS[CMPIF] bit will cause an interrupt request.

## 55.8.21 DMA Enable Register (SM0DMAEN - SM3DMAEN)

### 55.8.21.1 Offset

Register	Offset
SM0DMAEN	28h
SM1DMAEN	88h
SM2DMAEN	E8h
SM3DMAEN	148h

### 55.8.21.2 Diagram

### 55.8.21.3 Fields

Field	Function
15-10 —	RESERVED
9 VALDE	Value Registers DMA Enable  This read/write bit enables DMA write requests for the VALx and FRACVALx registers when STS[RF] is set. Reset clears this bit. 0b - DMA write requests disabled

Table continues on the next page...

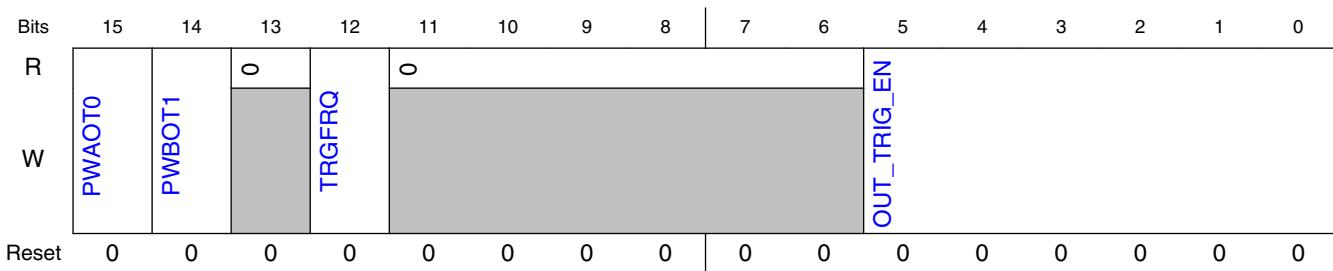

Field	Function
	1b - Enabled. DMA write requests for the VALx and FRACVALx registers enabled
8 FAND	<p>FIFO Watermark AND Control</p> <p>This read/write bit works in conjunction with the DMAEN[CAPTDE] field when it is set to watermark mode (DMAEN[CAPTDE] = 01). While DMAEN[CAxDE], DMAEN[CBxDE], and DMAEN[CXxDE] determine which FIFO watermarks the DMA read request is sensitive to, this bit determines if the selected watermarks are AND'ed together or OR'ed together in order to create the request.</p> <p>0b - Selected FIFO watermarks are OR'ed together. 1b - Selected FIFO watermarks are AND'ed together.</p>
7-6 CAPTDE	<p>Capture DMA Enable Source Select</p> <p>These read/write bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits.</p> <p>00b - Read DMA requests disabled. 01b - Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to also be set in order to determine to which watermark(s) the DMA request is sensitive. 10b - A local sync (VAL1 matches counter) sets the read DMA request. 11b - A local reload (STS[RF] being set) sets the read DMA request.</p>
5 CA1DE	<p>Capture A1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set both this bit and INTEN[CA1IE].</p>
4 CA0DE	<p>Capture A0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE].</p>
3 CB1DE	<p>Capture B1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE].</p>
2 CB0DE	<p>Capture B0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture B0 FIFO data when STS[CFB0] is set. Reset clears this bit. Do not set both this bit and INTEN[CB0IE].</p>
1 CX1DE	<p>Capture X1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture X1 FIFO data when STS[CFX1] is set. Reset clears this bit. Do not set both this bit and INTEN[CX1IE].</p>
0 CX0DE	<p>Capture X0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture X0 FIFO data when STS[CFX0] is set. Reset clears this bit. Do not set both this bit and INTEN[CX0IE].</p>

## 55.8.22 Output Trigger Control Register (SM0TCTRL - SM3TCTRL)

### 55.8.22.1 Offset

Register	Offset
SM0TCTRL	2Ah

W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

### 55.8.23.4 Fields

Field	Function
15-12 —	RESERVED
11-8 DIS0X	PWM_X Fault Disable Mask 0  Each of the four bits of this read/write field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_X output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. A reset sets all bits in this field.
7-4 DIS0B	PWM_B Fault Disable Mask 0  Each of the four bits of this read/write field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_B output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. A reset sets all bits in this field.
3-0 DIS0A	PWM_A Fault Disable Mask 0  Each of the four bits of this read/write field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_A output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. A reset sets all bits in this field.

## 55.8.24 Deadtime Count Register 0 (SM0DTCNT0 - SM3DTCNT0)

### 55.8.24.1 Offset

Register	Offset
SM0DTCNT0	30h
SM1DTCNT0	90h
SM2DTCNT0	F0h
SM3DTCNT0	150h

## 55.8.24.2 Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK\_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

## 55.8.24.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W																
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

## 55.8.24.4 Fields

Field	Function
15-0 DTCNT0	<p>The DTCNT0 field is interpreted differently depending on whether or not the fractional delays are being used (Set FRCTRL[FRAC23_EN] to 1 when MCTRL[IPOL]=0, or set FRCTRL[FRAC45_EN] to 1 when MCTRL[IPOL]=1). If the fractional delays are off, then the upper 5 bits of DTCNT0 are ignored and the remaining 11 bits are used to specify the number of cycles of deadtime. In this case the maximum value is 0x07FF which indicates 2047 cycles of deadtime. If the fractional delays are being used, then the upper 11 bits of DTCNT0 represent the number of whole cycles of deadtime and the lower 5 bits of each register represent the fractional cycle added to the whole number. In this case the maximum value is 0xFFFF which represents 2047 31/32 cycles of deadtime.</p> <p>The DTCNT0 field is used to control the deadtime during 0 to 1 transitions of the PWM_A output (assuming normal polarity).</p>

## 55.8.25 Deadtime Count Register 1 (SM0DTCNT1 - SM3DTCNT1)

### 55.8.25.1 Offset

Register	Offset
SM0DTCNT1	32h

Table continues on the next page...

## PWM register descriptions

Register	Offset
SM1DTCNT1	92h
SM2DTCNT1	F2h
SM3DTCNT1	152h

### 55.8.25.2 Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK\_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

### 55.8.25.3 Diagram

### 55.8.25.4 Fields

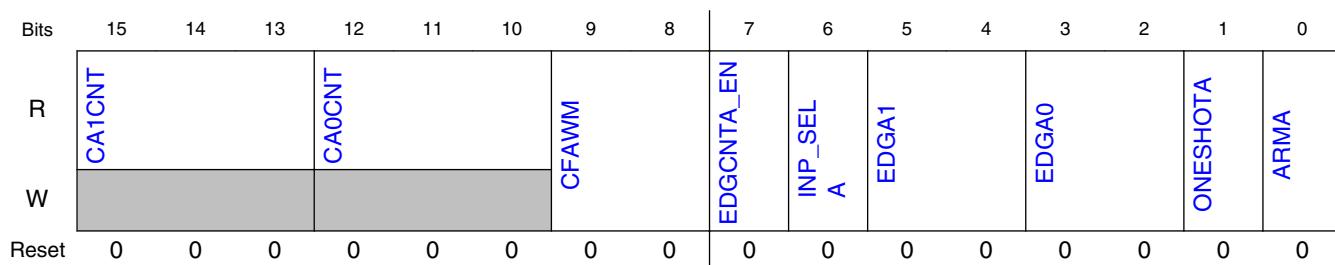

Field	Function
15-0 DTCNT1	<p>The DTCNT1 field is interpreted differently depending on whether or not the fractional delays are being used (Set FRCTRL[FRAC23_EN] to 1 when MCTRL[IPOL]=0, or set FRCTRL[FRAC45_EN] to 1 when MCTRL[IPOL]=1). If the fractional delays are off, then the upper 5 bits of DTCNT1 are ignored and the remaining 11 bits are used to specify the number of cycles of deadtime. In this case the maximum value is 0x07FF which indicates 2047 cycles of deadtime. If the fractional delays are being used, then the upper 11 bits of DTCNT1 represent the number of whole cycles of deadtime and the lower 5 bits of each register represent the fractional cycle added to the whole number. In this case the maximum value is 0xFFFF which represents 2047 31/32 cycles of deadtime.</p> <p>The DTCNT1 field is used to control the deadtime during 0 to 1 transitions of the PWM_B output (assuming normal polarity).</p>

## 55.8.26 Capture Control A Register (SM0CAPTCTRLA - SM3CAPTCTRLA)

### 55.8.26.1 Offset

Register	Offset
SM0CAPTCTRLA	34h
SM1CAPTCTRLA	94h
SM2CAPTCTRLA	F4h
SM3CAPTCTRLA	154h

### 55.8.26.2 Diagram

### 55.8.26.3 Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This bit enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6	Input Select A

Table continues on the next page...

## PWM register descriptions

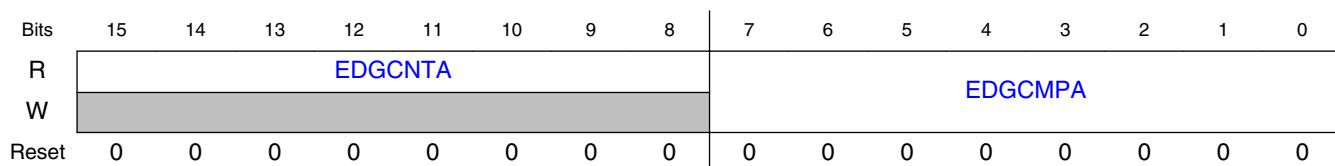

Field	Function
INP_SELA	<p>This bit selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit.</p> <p>0b - Raw PWM_A input signal selected as source.      1b - Edge Counter. Output of edge counter/compare selected as source. Note that when this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must still place a value other than 00 in either or both of the CAPTCTRLA[EDGA0] and/or CAPTCTRLA[EDGA1] fields in order to enable one or both of the capture registers.</p>
5-4 EDGA1	<p>Edge A 1</p> <p>These bits control the input capture 1 circuitry by determining which input edges cause a capture event.</p> <p>00b - Disabled      01b - Capture falling edges      10b - Capture rising edges      11b - Capture any edge</p>
3-2 EDGA0	<p>Edge A 0</p> <p>These bits control the input capture 0 circuitry by determining which input edges cause a capture event.</p> <p>00b - Disabled      01b - Capture falling edges      10b - Capture rising edges      11b - Capture any edge</p>
1 ONESHOTA	<p>One Shot Mode A</p> <p>This bit selects between free running and one shot mode for the input capture circuitry.</p> <p>0b - Free Running. Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.      1b - One Shot. One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and CAPTCTRLA[ARMA] is cleared. No further captures will be performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.</p>
0 ARMA	<p>Arm A</p> <p>Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event.</p> <p>0b - Input capture operation is disabled.      1b - Input capture operation as specified by CAPTCTRLA[EDGAX] is enabled.</p>

## 55.8.27 Capture Compare A Register (SM0CAPTCOMPA - SM3CAPTCOMPA)

12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], won't be set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This bit enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SEL_B	Input Select B This bit selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. Note that when this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must still place a value other than 00 in either or both of the CAPTCTRLB[EDGB0] and/or CAPTCTRLB[EDGB1] fields in order to enable one or both of the capture registers.
5-4 EDGB1	Edge B 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled

Table continues on the next page...

Field	Function
	01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0  These bits control the input capture 0 circuitry by determining which input edges cause a capture event.  00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B  This bit selects between free running and one shot mode for the input capture circuitry.  0b - Free Running. Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and CAPTCTRLB[ARMB] is cleared. No further captures will be performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.
0 ARMB	Arm B  Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event.  0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

## 55.8.29 Capture Compare B Register (SM0CAPTCOMPB - SM3CAPTCOMPB)

### 55.8.29.1 Offset

Register	Offset
SM0CAPTCOMPB	3Ah
SM1CAPTCOMPB	9Ah
SM2CAPTCOMPB	FAh
SM3CAPTCOMPB	15Ah

## 55.8.30.3 Fields

Field	Function
15-13 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO. (FIFO depth is 1.)
12-10 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO. (FIFO depth is 1.)
9-8 CFXWM	Capture X FIFOs Water Mark This field represents the water mark level for capture X FIFOs. The capture flags, STS[CFX1] and STS[CFX0], won't be set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELX	Input Select X This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_X input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. Note that when this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must still place a value other than 00 in either or both of the CAPTCTRLX[EDGX0] and/or CAPTCTRLX[EDGX1] fields in order to enable one or both of the capture registers.
5-4 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled

Table continues on the next page...

## PWM register descriptions

Field	Function
	01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	<p>One Shot Mode Aux</p> <p>This bit selects between free running and one shot mode for the input capture circuitry.</p> <p>0b - Free Running. Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.</p> <p>1b - One Shot. One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMX bit is cleared. No further captures will be performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMX bit is then cleared.</p>
0 ARMX	<p>Arm X</p> <p>Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. ## 55.8.31 Capture Compare X Register (SM0CAPTCOMPX - SM3CAPTCOMPX)

### 55.8.31.1 Offset

Register	Offset
SM0CAPTCOMPX	3Eh
SM1CAPTCOMPX	9Eh
SM2CAPTCOMPX	FEh
SM3CAPTCOMPX	15Eh

X pins have limited usability as input capture - see note on pin 3103

### 55.8.31.2 Diagram

### 55.8.31.3 Fields

Field	Function
15-8 EDGCNTX	Edge Counter X This read-only field contains the edge counter value for the PWM_X input capture circuitry.
7-0 EDGCMPPX	Edge Compare X This read/write field is the compare value associated with the edge counter for the PWM_X input capture circuitry.

## 55.8.32 Capture Value 0 Register (SM0CVAL0 - SM3CVAL0)

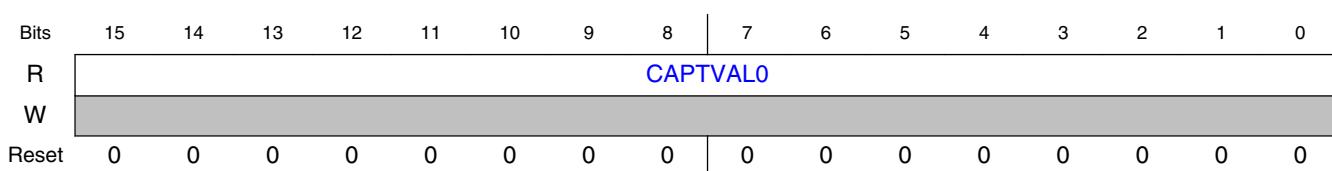

### 55.8.32.1 Offset

Register	Offset
SM0CVAL0	40h
SM1CVAL0	A0h
SM2CVAL0	100h
SM3CVAL0	160h

### 55.8.32.2 Function

Writing this register generates bus transfer error.

### 55.8.32.3 Diagram

### 55.8.32.4 Fields

Field	Function
15-0 CAPTVAL0	CAPTVAL0  This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLX[EDGX0]. Each capture will increase the value of CAPTCTRLX[CX0CNT] by 1 until the maximum value is reached. Each read of this register will decrease the value of CAPTCTRLX[CX0CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.33 Capture Value 0 Cycle Register (SM0CVAL0CYC - SM3CVAL0CYC)

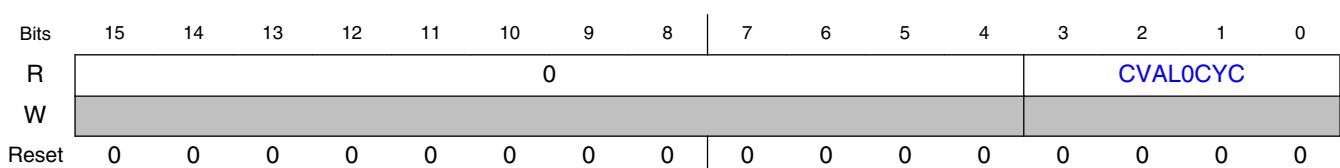

### 55.8.33.1 Offset

Register	Offset
SM0CVAL0CYC	42h
SM1CVAL0CYC	A2h
SM2CVAL0CYC	102h
SM3CVAL0CYC	162h

### 55.8.33.2 Function

Writing this register generates bus transfer error.

### 55.8.33.3 Diagram

### 55.8.33.4 Fields

Field	Function
15-4 —	RESERVED
3-0 CVAL0CYC	CVAL0CYC This read-only register stores the cycle number corresponding to the value captured in CVAL0. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

### 55.8.34 Capture Value 1 Register (SM0CVAL1 - SM3CVAL1)

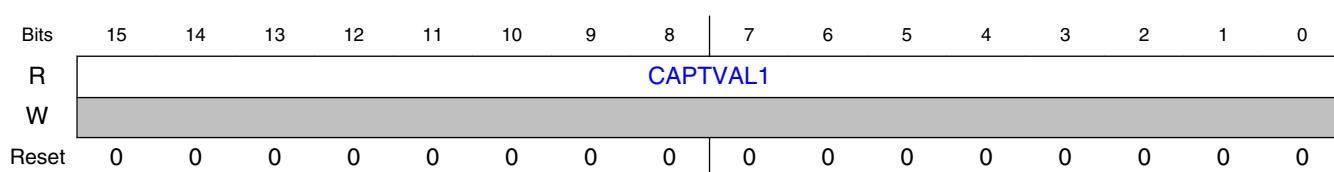

#### 55.8.34.1 Offset

Register	Offset
SM0CVAL1	44h
SM1CVAL1	A4h
SM2CVAL1	104h
SM3CVAL1	164h

#### 55.8.34.2 Function

Writing this register generates bus transfer error.

#### 55.8.34.3 Diagram

## 55.8.34.4 Fields

Field	Function
15-0 CAPTVAL1	CAPTVAL1  This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLX[EDGX1]. Each capture increases the value of CAPTCTRLX[CX1CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLX[CX1CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.35 Capture Value 1 Cycle Register (SM0CVAL1CYC - SM3CVAL1CYC)

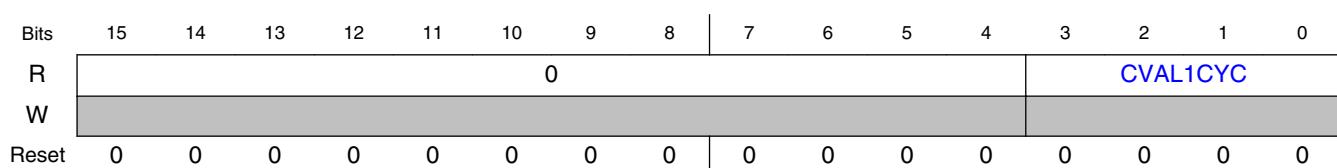

### 55.8.35.1 Offset

Register	Offset
SM0CVAL1CYC	46h
SM1CVAL1CYC	A6h
SM2CVAL1CYC	106h
SM3CVAL1CYC	166h

### 55.8.35.2 Function

Writing this register generates bus transfer error.

### 55.8.35.3 Diagram

### 55.8.35.4 Fields

Field	Function
15-4 —	RESERVED
3-0 CVAL1CYC	CVAL1CYC This read-only register stores the cycle number corresponding to the value captured in CVAL1. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

### 55.8.36 Capture Value 2 Register (SM0CVAL2 - SM3CVAL2)

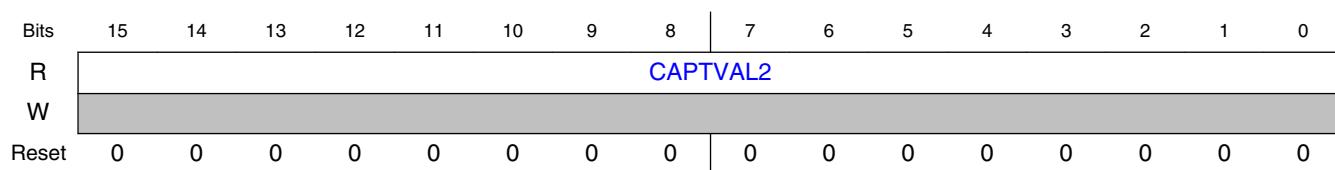

#### 55.8.36.1 Offset

Register	Offset
SM0CVAL2	48h
SM1CVAL2	A8h
SM2CVAL2	108h
SM3CVAL2	168h

#### 55.8.36.2 Function

Writing this register generates bus transfer error.

#### 55.8.36.3 Diagram

## 55.8.36.4 Fields

Field	Function
15-0 CAPTVAL2	CAPTVAL2 This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLA[EDGA0]. Each capture increases the value of CAPTCTRLA[CA0CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLA[CA0CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.37 Capture Value 2 Cycle Register (SM0CVAL2CYC - SM3CVAL2CYC)

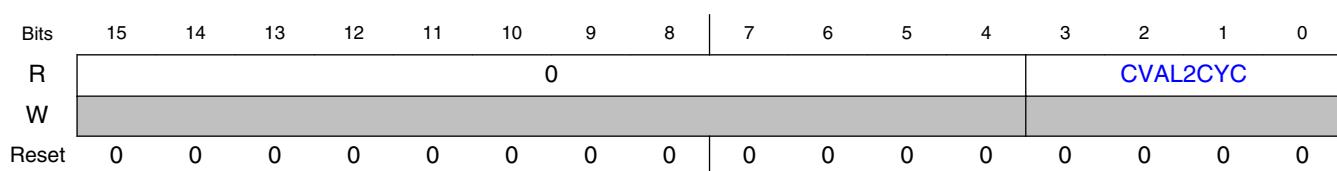

### 55.8.37.1 Offset

Register	Offset
SM0CVAL2CYC	4Ah
SM1CVAL2CYC	AAh
SM2CVAL2CYC	10Ah
SM3CVAL2CYC	16Ah

### 55.8.37.2 Function

Writing this register generates bus transfer error.

### 55.8.37.3 Diagram

### 55.8.37.4 Fields

Field	Function
15-4 —	RESERVED
3-0 CVAL2CYC	CVAL2CYC This read-only register stores the cycle number corresponding to the value captured in CVAL2. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

### 55.8.38 Capture Value 3 Register (SM0CVAL3 - SM3CVAL3)

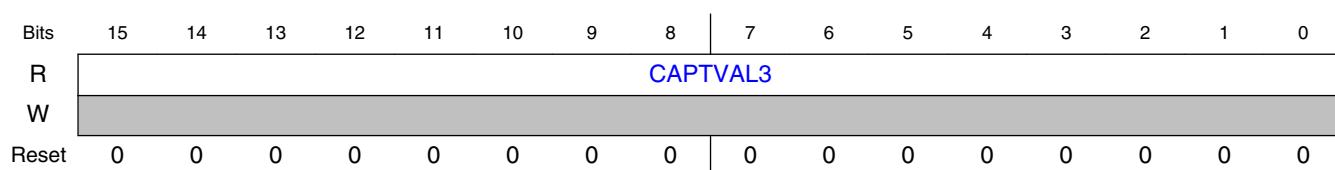

#### 55.8.38.1 Offset

Register	Offset
SM0CVAL3	4Ch
SM1CVAL3	ACh
SM2CVAL3	10Ch
SM3CVAL3	16Ch

#### 55.8.38.2 Function

Writing this register generates bus transfer error.

#### 55.8.38.3 Diagram

## 55.8.38.4 Fields

Field	Function
15-0 CAPTVAL3	CAPTVAL3 This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLA[EDGA1]. Each capture increases the value of CAPTCTRLA[CA1CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLA[CA1CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.39 Capture Value 3 Cycle Register (SM0CVAL3CYC - SM3CVAL3CYC)

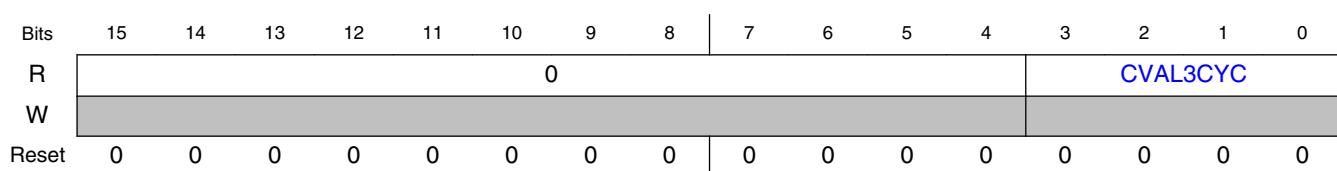

### 55.8.39.1 Offset

Register	Offset
SM0CVAL3CYC	4Eh
SM1CVAL3CYC	A Eh
SM2CVAL3CYC	10Eh
SM3CVAL3CYC	16Eh

### 55.8.39.2 Function

Writing this register generates bus transfer error.

### 55.8.39.3 Diagram

## 55.8.39.4 Fields

Field	Function
15-4 —	RESERVED
3-0 CVAL3CYC	CVAL3CYC This read-only register stores the cycle number corresponding to the value captured in CVAL3. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

## 55.8.40 Capture Value 4 Register (SM0CVAL4 - SM3CVAL4)

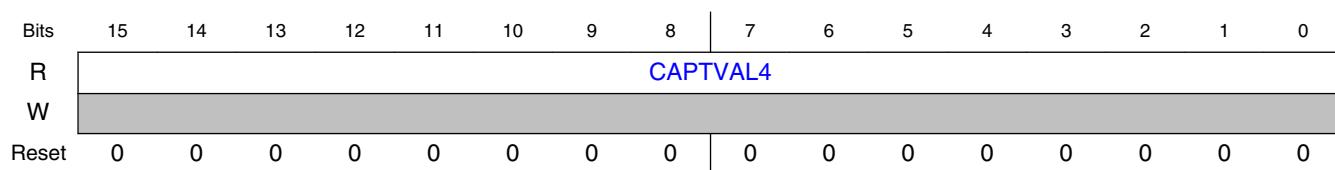

### 55.8.40.1 Offset

Register	Offset
SM0CVAL4	50h
SM1CVAL4	B0h
SM2CVAL4	110h
SM3CVAL4	170h

### 55.8.40.2 Function

Writing this register generates bus transfer error.

### 55.8.40.3 Diagram

## 55.8.40.4 Fields

Field	Function
15-0 CAPTVAL4	CAPTVAL4  This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLB[EDGB0]. Each capture increases the value of CAPTCTRLB[CB0CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLB[CB0CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.41 Capture Value 4 Cycle Register (SM0CVAL4CYC - SM3CVAL4CYC)

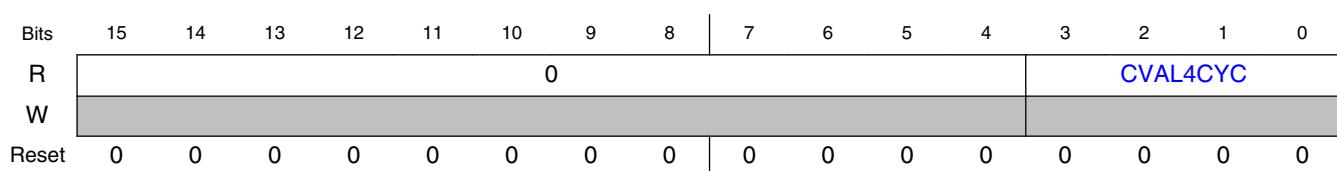

### 55.8.41.1 Offset

Register	Offset
SM0CVAL4CYC	52h
SM1CVAL4CYC	B2h
SM2CVAL4CYC	112h
SM3CVAL4CYC	172h

### 55.8.41.2 Function

Writing this register generates bus transfer error.

### 55.8.41.3 Diagram

### 55.8.41.4 Fields

Field	Function
15-4 —	RESERVED
3-0 CVAL4CYC	CVAL4CYC This read-only register stores the cycle number corresponding to the value captured in CVAL4. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

### 55.8.42 Capture Value 5 Register (SM0CVAL5 - SM3CVAL5)

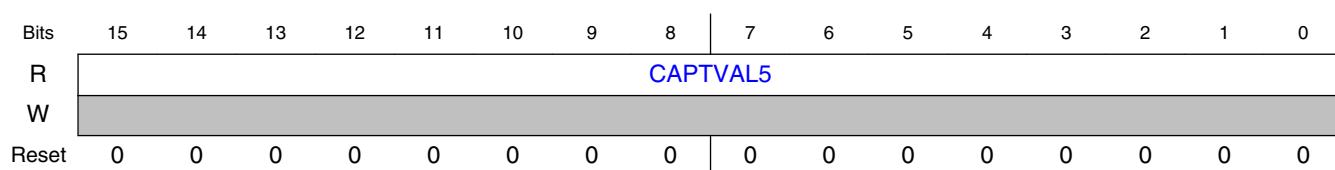

#### 55.8.42.1 Offset

Register	Offset
SM0CVAL5	54h
SM1CVAL5	B4h
SM2CVAL5	114h
SM3CVAL5	174h

#### 55.8.42.2 Function

Writing this register generates bus transfer error.

#### 55.8.42.3 Diagram

## 55.8.42.4 Fields

Field	Function
15-0 CAPTVAL5	CAPTVAL5  This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLB[EDGB1]. Each capture increases the value of CAPTCTRLB[CB1CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLB[CB1CNT] by 1 until 0 is reached. This register is not byte accessible.

## 55.8.43 Capture Value 5 Cycle Register (SM0CVAL5CYC - SM3CVAL5CYC)

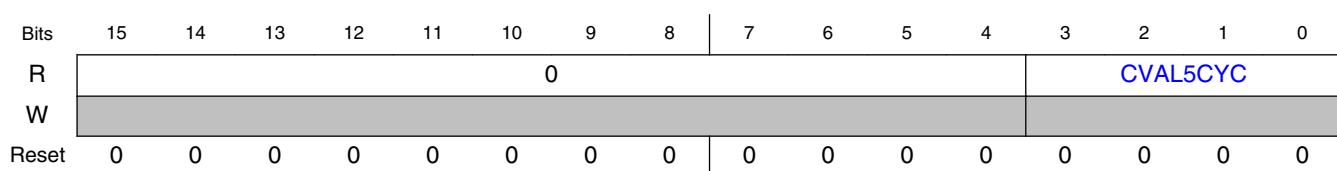

### 55.8.43.1 Offset

Register	Offset
SM0CVAL5CYC	56h
SM1CVAL5CYC	B6h
SM2CVAL5CYC	116h
SM3CVAL5CYC	176h

### 55.8.43.2 Function

Writing this register generates bus transfer error.

### 55.8.43.3 Diagram

### 55.8.43.4 Fields

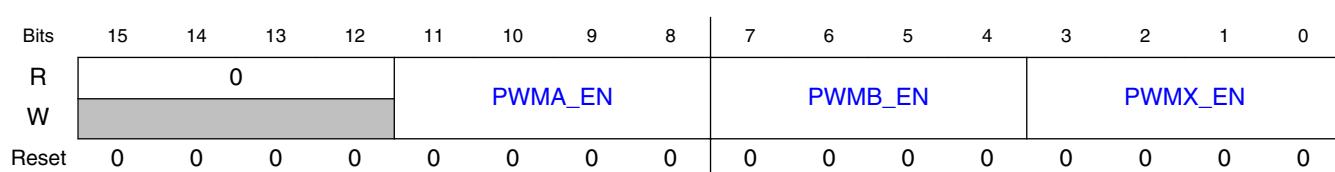

Field	Function
15-4 —	RESERVED
3-0 CVAL5CYC	CVAL5CYC This read-only register stores the cycle number corresponding to the value captured in CVAL5. This register is incremented each time the counter is loaded with the INIT value at the end of a PWM modulo cycle.

### 55.8.44 Output Enable Register (OUTEN)

#### 55.8.44.1 Offset

Register	Offset
OUTEN	180h

#### 55.8.44.2 Diagram

#### 55.8.44.3 Fields

Field	Function
15-12 —	RESERVED
11-8 PWMA_EN	PWM_A Output Enables The four bits of this field enable the PWM_A outputs of submodules 3-0, respectively. These bits should be set to 0 (output disabled) when a PWM_A pin is being used for input capture. 0000b - PWM_A output disabled. 0001b - PWM_A output enabled.

Table continues on the next page...

## PWM register descriptions

Field	Function
7-4 PWMB_EN	<p>PWM_B Output Enables</p> <p>The four bits of this field enable the PWM_B outputs of submodules 3-0, respectively. These bits should be set to 0 (output disabled) when a PWM_B pin is being used for input capture.</p> <p>0000b - PWM_B output disabled. 0001b - PWM_B output enabled.</p>
3-0 PWMX_EN	<p>PWM_X Output Enables</p> <p>The four bits of this field enable the PWM_X outputs of submodules 3-0, respectively. These bits should be set to 0 (output disabled) when a PWM_X pin is being used for input capture or deadtime correction.</p> <p>0000b - PWM_X output disabled. 0001b - PWM_X output enabled.</p>

## 55.8.45 Mask Register (MASK)

### 55.8.45.1 Offset

Register	Offset
MASK	182h

### 55.8.45.2 Function

MASK is double buffered and does not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading MASK reads the buffered values and not necessarily the values currently in effect. This double buffering can be overridden by setting the UPDATE\_MASK bits.

### 55.8.45.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UPDATE\_MASK

## 55.8.45.4 Fields

Field	Function
15-12 UPDATE_MASK	<p>Update Mask Bits Immediately</p> <p>The four bits mask the PWM_X outputs of submodules 3-0, respectively. The four bits of this field force the MASK* bits to be immediately updated within submodules 3-0, respectively, without waiting for a FORCE_OUT event. These self-clearing bits always read as zero. Software may write to any or all of these bits and may set these bits in the same write operation that updates the MASKA, MASKB, and MASKX fields of this register.</p> <p>0000b - Normal operation. MASK* bits within the corresponding submodule are not updated until a FORCE_OUT event occurs within the submodule.</p> <p>0001b - Immediate operation. MASK* bits within the corresponding submodule are updated on the following clock edge after setting this bit.</p>
11-8 MASKA	<p>PWM_A Masks</p> <p>The four bits of this field mask the PWM_A outputs of submodules 3-0, respectively, forcing the output to logic 0 prior to consideration of the output polarity.</p> <p>0000b - PWM_A output normal. 0001b - PWM_A output masked.</p>
7-4 MASKB	<p>PWM_B Masks</p> <p>The four bits of this field mask the PWM_B outputs of submodules 3-0, respectively, forcing the output to logic 0 prior to consideration of the output polarity.</p> <p>0000b - PWM_B output normal. 0001b - PWM_B output masked.</p>
3-0 MASKX	<p>PWM_X Masks</p> <p>The four bits of this field mask the PWM_X outputs of submodules 3-0, respectively, forcing the output to logic 0 prior to consideration of the output polarity.</p> <p>0000b - PWM_X output normal. 0001b - PWM_X output masked.</p>

## 55.8.46 Software Controlled Output Register (SWCOUT)

### 55.8.46.1 Offset

Register	Offset
SWCOUT	184h

## 55.8.46.2 Function

These bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

## 55.8.46.3 Diagram

## 55.8.46.4 Fields

Field	Function
15-8 —	RESERVED
7 SM3OUT23	Submodule 3 Software Controlled Output 23  This bit is only used when DTSRCSEL[SM3SEL23] is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM23.
6 SM3OUT45	Submodule 3 Software Controlled Output 45  This bit is only used when DTSRCSEL[SM3SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM45.
5 SM2OUT23	Submodule 2 Software Controlled Output 23  This bit is only used when DTSRCSEL[SM2SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM23.
4 SM2OUT45	Submodule 2 Software Controlled Output 45  This bit is only used when DTSRCSEL[SM2SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM45.

Table continues on the next page...

Field	Function
3 SM1OUT23	Submodule 1 Software Controlled Output 23  This bit is only used when DTSRCSEL[SM1SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM23.
2 SM1OUT45	Submodule 1 Software Controlled Output 45  This bit is only used when DTSRCSEL[SM1SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM45.
1 SM0OUT23	Submodule 0 Software Controlled Output 23  This bit is only used when DTSRCSEL[SM0SEL23] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM23. 1b - A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM23.
0 SM0OUT45	Submodule 0 Software Controlled Output 45  This bit is only used when DTSRCSEL[SM0SEL45] is set to b10. It allows software control of which signal is supplied to the deadtime generator of that submodule.  0b - A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM45. 1b - A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM45.

## 55.8.47 PWM Source Select Register (DTSRCSEL)

### 55.8.47.1 Offset

Register	Offset
DTSRCSEL	186h

### 55.8.47.2 Function

The PWM source select bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

### 55.8.47.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 55.8.48 Master Control Register (MCTRL)

### 55.8.48.1 Offset

Register	Offset
MCTRL	188h

### 55.8.48.2 Function

In every 4-bit field in this register, each bit acts on a separate submodule. Accordingly, the description of every bitfield refers to the effect of an individual bit.

### 55.8.48.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R									0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	I POL	RUN	0	C LDOK	L DOK
--	-------	-----	---	--------	-------

### 55.8.48.4 Fields

Field	Function
15-12 I POL	<p>Current Polarity</p> <p>The four buffered read/write bits of this field correspond to submodules 3-0, respectively. Each bit selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. MCTRL[I POL] is ignored in independent mode.</p> <p>MCTRL[I POL] does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading MCTRL[I POL] reads the buffered value and not necessarily the value currently in effect.</p> <p>0000b - PWM23 is used to generate complementary PWM pair in the corresponding submodule. 0001b - PWM45 is used to generate complementary PWM pair in the corresponding submodule.</p>
11-8 RUN	<p>Run</p> <p>The four read/write bits of this field enable the clocks to the PWM generator of submodules 3-0, respectively. The corresponding MCTRL[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset and PWM outputs are held. A reset clears this field.</p> <p>0000b - PWM counter is stopped, but PWM outputs will hold the current state. 0001b - PWM counter is started in the corresponding submodule.</p>
7-4 C LDOK	<p>Clear Load Okay</p> <p>The 4 bits of CLDOK field correspond to submodules 3-0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL[L DOK]. Write a 1 to CLDOK to clear the corresponding MCTRL[L DOK] bit. If a reload occurs within a submodule with the corresponding MCTRL[L DOK] bit set at the same time that MCTRL[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL[L DOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.</p>
3-0 L DOK	<p>Load Okay</p> <p>The 4 bits of L DOK field correspond to submodules 3-0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or immediately if CTRL[LDMOD] is set. Set the corresponding MCTRL[L DOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx, INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the corresponding MCTRL[L DOK] bit is set.</p> <p>In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is only necessary to set the L DOK bit corresponding to submodule0; however, it is recommended to also set the L DOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules.</p>

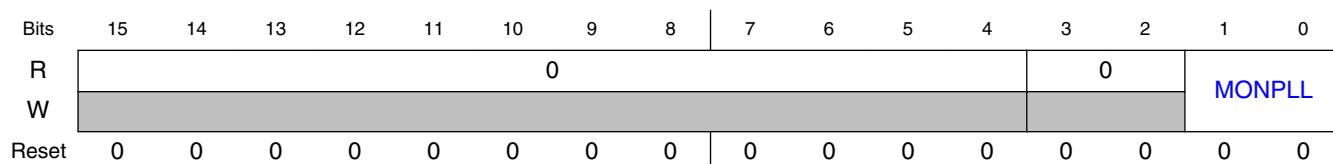

Field	Function
	<p>The MCTRL[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT, FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field.</p> <p>0000b - Do not load new values. 0001b - Load prescaler, modulus, and PWM values of the corresponding submodule.</p>

## 55.8.50 Fault Control Register (FCTRL0)

### 55.8.50.1 Offset

Register	Offset
FCTRL0	18Ch

### 55.8.50.2 Function

For every 4-bit field in this register, the bits act on the fault inputs in order. For example, FLVL bits 15-12 act on faults 3-0, respectively.

### 55.8.50.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FLVL				FAUTO				FSAFE				FIE			
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## 55.8.50.4 Fields

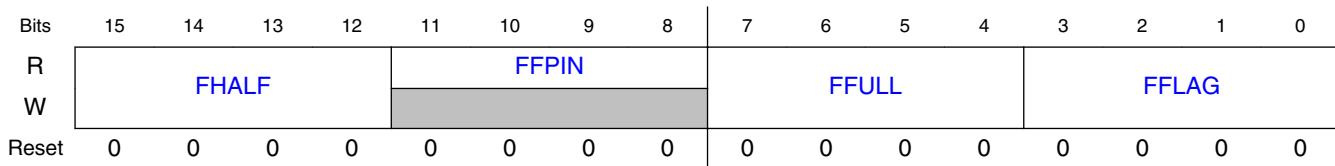

Field	Function
15-12 FLVL	<p>Fault Level</p> <p>The four read/write bits of this field select the active logic level of the individual fault inputs 3-0, respectively. A reset clears this field.</p> <p>0000b - A logic 0 on the fault input indicates a fault condition. 0001b - A logic 1 on the fault input indicates a fault condition.</p>
11-8 FAUTO	<p>Automatic Fault Clearing</p> <p>The four read/write bits of this field select automatic or manual clearing of faults 3-0, respectively. A reset clears this field.</p> <p>0000b - Manual fault clearing. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared. This is further controlled by FCTRL[FSAFE]. 0001b - Automatic fault clearing. PWM outputs disabled by this fault are enabled when FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFLAGx]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared.</p>
7-4 FSAFE	<p>Fault Safety Mode</p> <p>These read/write bits select the safety mode during manual fault clearing. A reset clears this field.</p> <p>FSTS[FFPINx] may indicate a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency.</p> <p>0000b - Normal mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFPINx]. If neither FHALF nor FFULL is set then the fault condition cannot be cleared. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAPn). 0001b - Safe mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear and FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FHALF nor FFULL is set, then the fault condition cannot be cleared.</p>
3-0 FIE	<p>Fault Interrupt Enables</p> <p>This read/write field enables CPU interrupt requests generated by the FAULTx pins. A reset clears this field.</p> <p><b>NOTE:</b> The fault protection circuit is independent of the FIEx bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register.</p> <p>0000b - FAULTx CPU interrupt requests disabled. 0001b - FAULTx CPU interrupt requests enabled.</p>

## 55.8.51 Fault Status Register (FSTS0)

### 55.8.51.1 Offset

Register	Offset
FSTS0	18Eh

### 55.8.51.2 Diagram

### 55.8.51.3 Fields

Field	Function
15-12 FHALF	<p>Half Cycle Fault Recovery</p> <p>These read/write bits are used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition.</p> <p><b>NOTE:</b> Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible.</p> <p>0000b - PWM outputs are not re-enabled at the start of a half cycle. 0001b - PWM outputs are re-enabled at the start of a half cycle (as defined by VAL0).</p>
11-8 FFPIN	<p>Filtered Fault Pins</p> <p>These read-only bits reflect the current state of the filtered FAULTx pins converted to high polarity. A logic 1 indicates a fault condition exists on the filtered FAULTx pin. A reset has no effect on this field.</p>
7-4 FFULL	<p>Full Cycle</p> <p>These read/write bits are used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition.</p> <p><b>NOTE:</b> Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible.</p> <p>0000b - PWM outputs are not re-enabled at the start of a full cycle 0001b - PWM outputs are re-enabled at the start of a full cycle</p>
3-0 FFLAG	<p>Fault Flags</p> <p>These read-only flag is set within two CPU cycles after a transition to active on the FAULTx pin. Clear this bit by writing a logic one to it. A reset clears this field. While the reset value is 0, these bits may be set to 1 by the time they can be read depending on the state of the fault input signals.</p> <p>0000b - No fault on the FAULTx pin. 0001b - Fault on the FAULTx pin.</p>

## 55.8.52 Fault Filter Register (FFILT0)

### 55.8.52.1 Offset

Register	Offset
FFILT0	190h

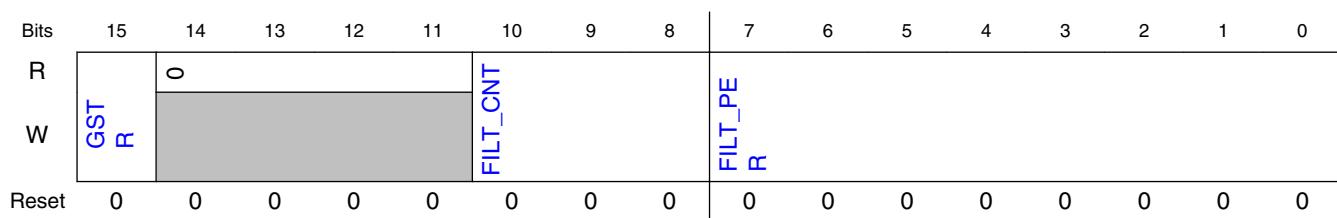

### 55.8.52.2 Function

The settings in this register are shared among each of the fault input filters within the fault channel.

Input filter considerations include:

- The FILT\_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT\_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT\_CNT+3 power.
- The values of FILT\_PER and FILT\_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT\_PER to a non-zero value) introduces a latency of ((FILT\_CNT+4) x FILT\_PER x IPBus clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

### 55.8.52.3 Diagram

### 55.8.52.4 Fields

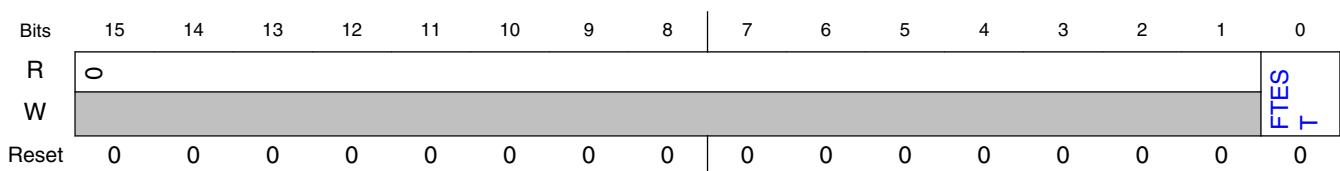

Field	Function
15 GSTR	Fault Glitch Stretch Enable  This bit is used to enable the fault glitch stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags.  0b - Fault input glitch stretching is disabled. 1b - Input fault signals will be stretched to at least 2 IPBus clock cycles.
14-11 —	RESERVED
10-8 FILT_CNT	Fault Filter Count  These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bitfield value of 0-7 represents 3-10 samples, respectively. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Fault Filter Period  This 8-bit field applies universally to all fault inputs.  These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency.  <b>NOTE:</b> When changing values for FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

### 55.8.53 Fault Test Register (FTST0)

#### 55.8.53.1 Offset

Register	Offset
FTST0	192h

#### 55.8.53.2 Diagram

### 55.8.53.3 Fields

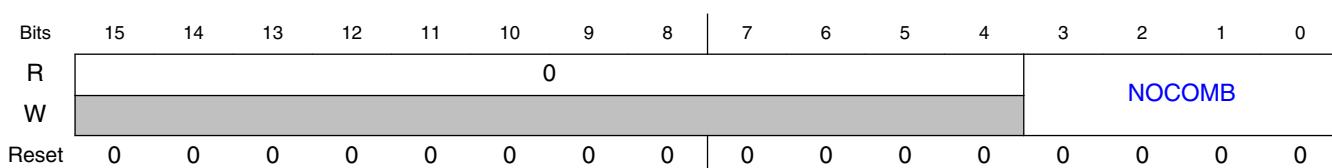

Field	Function
15-1 —	RESERVED
0 FTEST	Fault Test  This read/write bit is used to simulate a fault condition. Setting this bit causes a simulated fault to be sent into all of the fault filters. The condition propagates to the fault flags and possibly the PWM outputs depending on the DISMAPn settings. Clearing this bit removes the simulated fault condition.  0b - No fault 1b - Cause a simulated fault

### 55.8.54 Fault Control 2 Register (FCTRL20)

#### 55.8.54.3 Fields

Field	Function
15-4 —	RESERVED
3-0	No Combinational Path From Fault Input To PWM Output

## PWM register descriptions

Field	Function
NOCOMB	<p>This read/write field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP0 and DISMAP1). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault.</p> <p>0000b - There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs.</p> <p>0001b - The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.</p>

### 56.2 Overview

The enhanced quadrature decoder module interfaces to position/speed sensors that are used in industrial motor control applications. Using 5 input signals (PHASEA, PHASEB, INDEX, TRIGGER, and HOME) from those position/speed sensors, the quadrature decoder module decodes shaft position, revolution count, and speed.

#### 56.2.1 System Block Diagram

The next figure shows the block diagram of the quad decoder module integrated into an SoC.

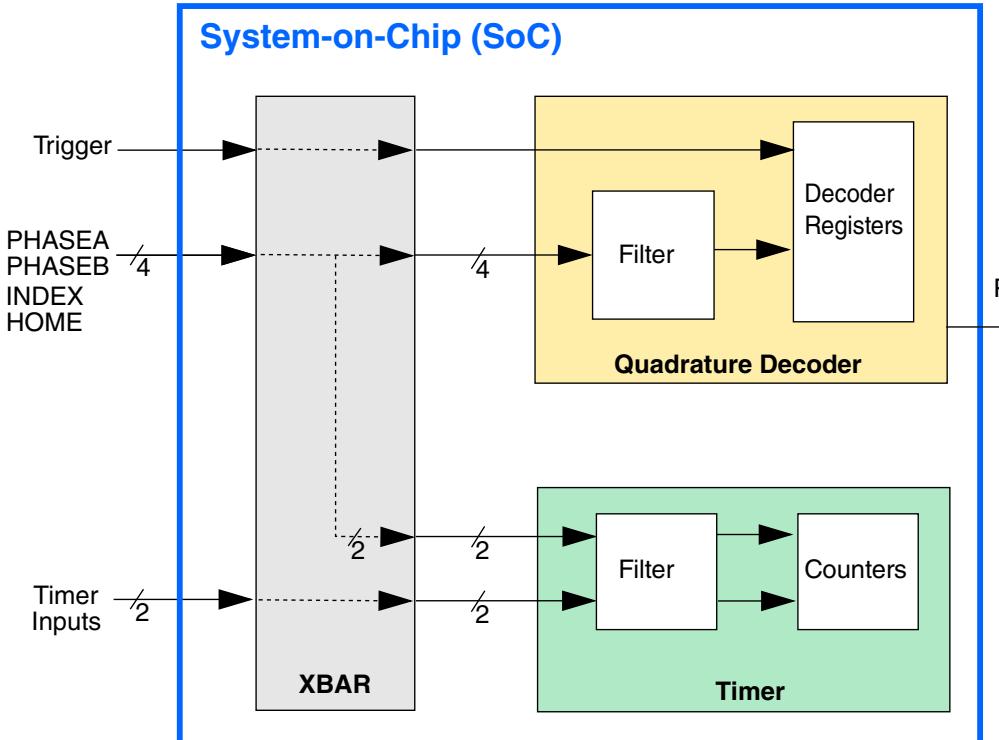

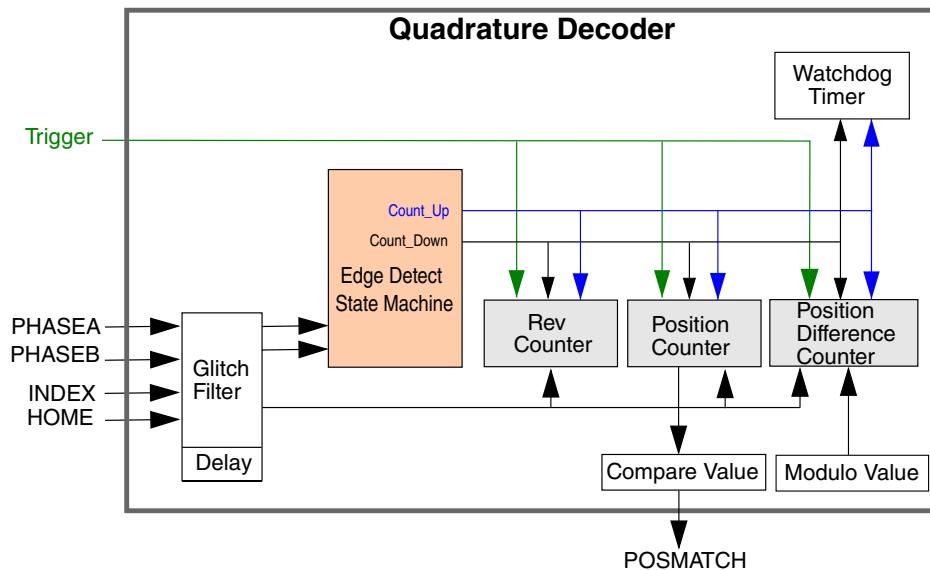

Figure 56-1. System Block Diagram

## 56.2.2 Features

- Includes logic to decode quadrature signals
- Inputs can be connected to a general purpose timer to make low speed velocity measurements
- Configurable digital filter for inputs
- Quadrature decoder filter can be bypassed
- 32-bit position counter capable of modulo counting
- Position counter can be initialized by software or external events
- 16-bit position difference register
- Compare function can indicate when shaft has reached a defined position
- A watchdog timer can detect a non-rotating shaft condition
- Preloadable 16-bit revolution counter
- Maximum count frequency equals the peripheral clock rate

## 56.2.3 Decoder Block Diagram

**Figure 56-2. Quad Decoder Block Diagram**

### 56.2.3.1 Glitch Filter

Because the quad decoder logic must sense signal transitions, the signal inputs are first run through a glitch filter. This glitch filter has a digital delay line, which samples multiple time points on the signal and verifies a stable new signal state, before outputting this new signal state to the internal quad decoder logic. To adapt to a variety of signal bandwidths, the sample rate of this delay line is programmable.

### 56.2.3.2 Edge Detect State Machine

The edge detect state machine looks for changes in the 4 possible states of the filtered PHASEA and PHASEB inputs, which are used to calculate the direction of motion. This information is formatted as Count\_Up and Count\_Down signals. Each counter has its own hold register. These signals are routed into up to 3 up/down counters:

- Position counter
- Revolution counter
- Position difference counter

### 56.2.3.3 Position Counter

The 32-bit position counter calculates up or down on every count pulse, generated by the difference of PHASEA and PHASEB. The position counter acts as an integration\_info, whose count value is proportional to position. The direction of the count is determined by the Count\_Up and Count\_Down signals. Position counters may be initialized to a predetermined value by one of 3 different methods:

- Software-triggered event
- INDEX signal transition
- HOME signal transition

The INDEX and HOME signals can be programmed to interrupt the processor. Whenever the position counters (UPOS or LPOS) are read, a snapshot of the

- position counter
- position difference counter
- revolution counter

are each placed into their respective hold registers.

### 56.2.3.4 Position Difference Counter

The 16-bit position difference counter contains the position difference value occurring between each read of the position register. The position register counts up or down on every count pulse. The position difference counter acts as a differentiator, whose count value is proportional to the change in position since the last time the position counter was read.

When the position registers, the position difference counter, or the revolution counter is read, the position difference counter's contents are copied into the position difference hold register (POSDH) and the position difference counter is cleared.

### 56.2.3.5 Position Difference Counter Hold

The Position Difference Counter Hold register stores a copy of the position difference counter at the time that the position register was read. When the position register, the position difference counter, or the revolution counter is read, the position difference counter's contents are copied into the position difference hold register (POSDH), and the position difference counter is cleared.

### 56.2.3.6 Revolution Counter

The 16-bit up/down revolution counter is intended to count or integrate revolutions by counting index pulses. The direction of the count is determined by the Count\_Up and Count\_Down signals, determined by the Phase A and B inputs. A different count direction on the rising and falling edges of the index pulse indicates that the quad encoder changed direction on the index pulse.

### 56.2.3.7 Watchdog Timer

The watchdog timer ensures that the algorithm is indicating motion in the shaft; 2 successive counts indicate proper operation and will reset the timer.

- The timeout value is programmable.
- When a timeout occurs, an interrupt to the processor can be generated.

### 56.2.3.8 Pulse Accumulator Functionality

The logic can be programmed to integrate only selected transitions of the PHASEA signal. In this way, the position counter can be used as a pulse accumulator.

- The count direction is up.
- The pulse accumulator can also optionally be initialized by the INDEX input.

## 56.3 Functional Description

The next timing diagram shows the basic operation of a quadrature incremental position quad decoder.

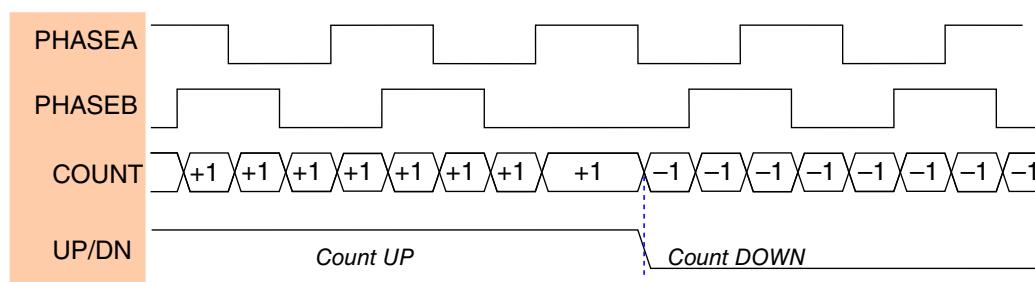

Figure 56-3. Quad Decoder Signals

### 56.3.1 Positive versus Negative Direction

A typical quad encoder has 3 outputs: PHASEA signal, PHASEB signal, INDEX pulse (not shown).

- If PHASEA leads PHASEB, then motion is in the positive direction.
- If PHASEA trails PHASEB, then motion is in the negative direction.

Transitions on these phases can be integrated to yield position or differentiated to yield velocity. The quad decoder is designed to perform these functions in hardware.

### 56.3.2 Prescaler for Slow or Fast Speed Measurement

- For applications with a fast moving shaft encoder, the speed can be computed by calculating the change in the position counter per unit time, or by reading the position difference counter register (POSD) and calculating speed.
- For applications with slow motor speeds and low line count quad encoders, the timer module enables high resolution velocity measurements by measuring the time period between quad phases.
  - The timer module uses a 16-bit free running counter operated from a prescaled version of the IPBus clock.
  - The prescaler divides the IPBus clock by values ranging from 1 to 128. A 60 MHz IPBus clock frequency would yield a resolution of from 17 ns to 2.1  $\mu$ s and a maximum count period of from 1.09 ms to 140 ms. For example, with a 1000-tooth decoder, speeds could be calculated down to 0.11 rpm using a prescaler.

### 56.3.3 Holding Registers and Initializing Registers

Hold registers are associated with 3 types of counters:

- Position
- Position difference
- Revolution

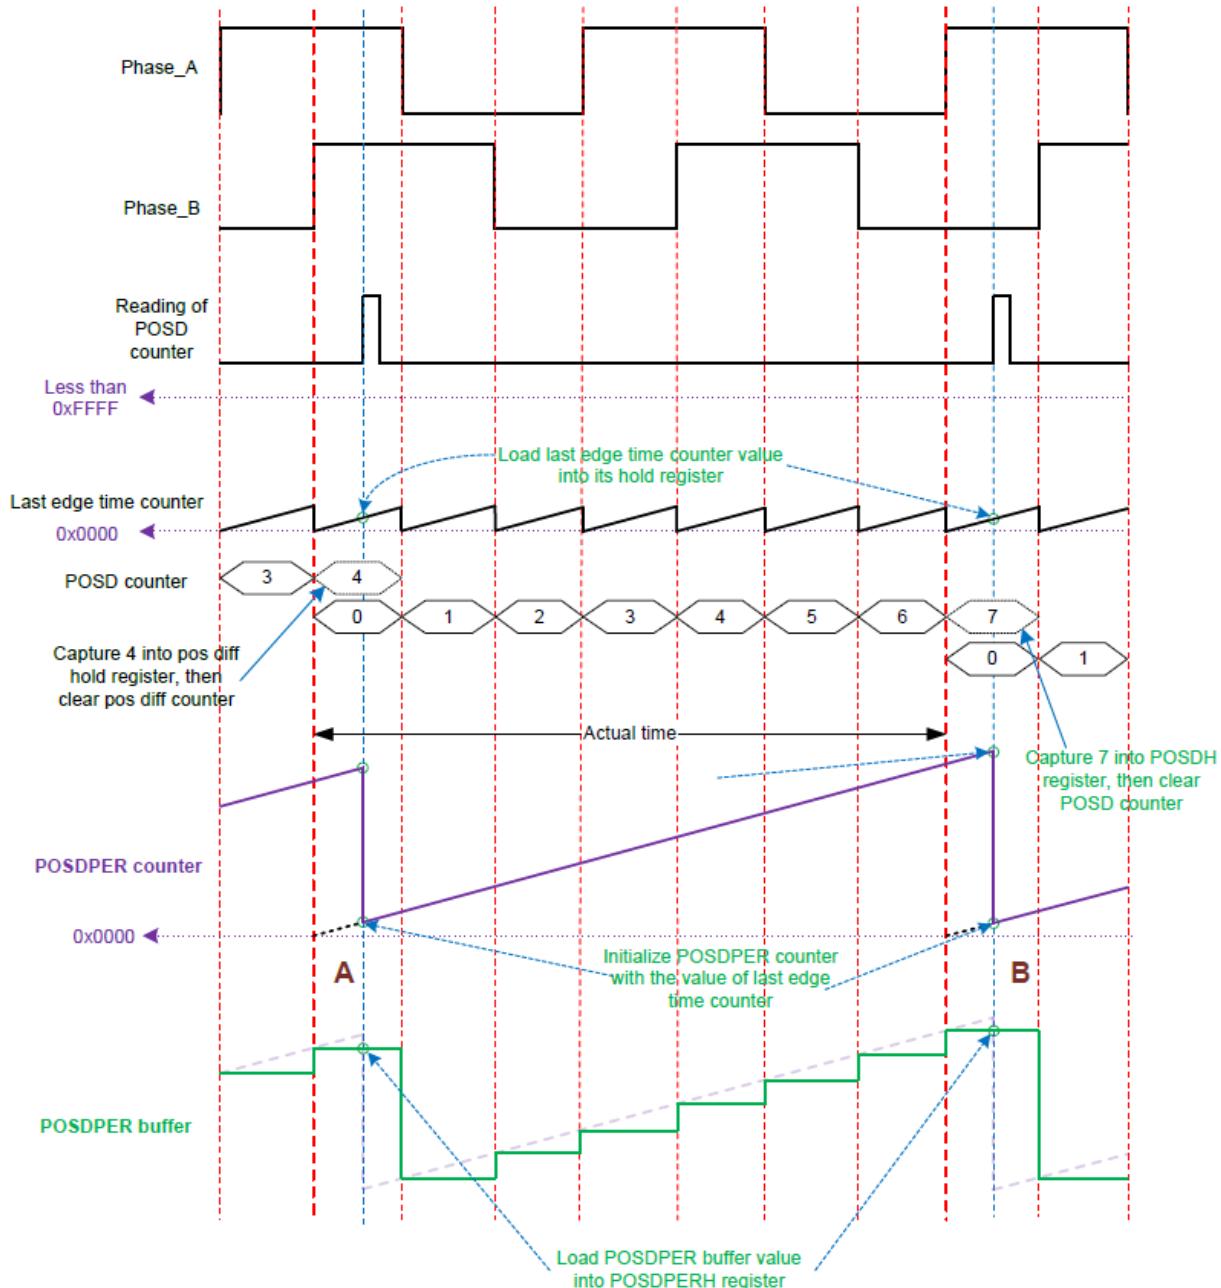

When any of the counter registers are read, the contents of each counter register is written to the corresponding hold register. Taking a snapshot of the counters' values allows a consistent view of a system's position and the velocity to be attained. To capture a time stamp of when these registers are read, use the POSMATCH output with a timer channel.

The position counter is 32 bits wide. To ensure that the position counter can be reliably initialized with two 16-bit accesses, two registers (an upper and a lower initialization register) are provided. The upper initialization register (UINIT) and lower initialization register (LINIT) should be loaded with the desired value. Next, the position counter can

be loaded by writing 1 to the Software-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[SWIP]). Alternatively, either the INDEX-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[XIP]) or the Enable HOME to Initialize Position Counters UPOS and LPOS bit (CTRL[HIP]) can enable the position counter to be initialized in response to a HOME or INDEX signal transition.

### 56.3.4 Speed Measurement Method

This section explains speed measurement method. It includes speed measurement algorithm.

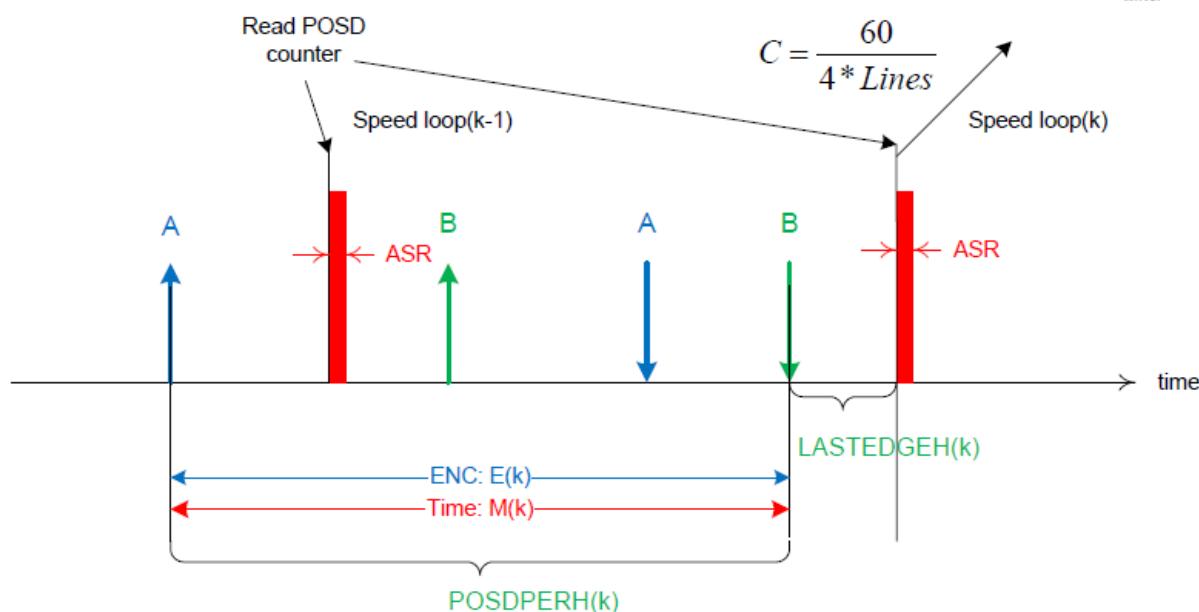

**Figure 56-4. Counters behavior and updating mechanism**

A reading of POSD occurs at time point A and it also occurs at time point B. “Actual time” represents the time duration between the first phase\_a/b edges right before time point A and B. At time point B, after reading POSD register, POSDPERH contains the time length of “Actual time” and POSDH contains the value of phase\_a/b pulses within that “Actual time”, speed can be calculated just based on POSDPERH and POSDH. A visualized explanation of speed measurement with this method is shown in figure below.

$$speed = \left( \frac{E(k)}{M(k)} * C \right) RPM$$

$$E(k) = POSDH(k) = 3$$

$$M(k) = POSDPERH(k) * T_{timer}$$

**Figure 56-5. High speed measurement with method**

#### 56.3.4.1 Speed calculation algorithm

However, in order to cover all the cases in real applications, a simple speed measurement algorithm is necessary. Below is the algorithm.

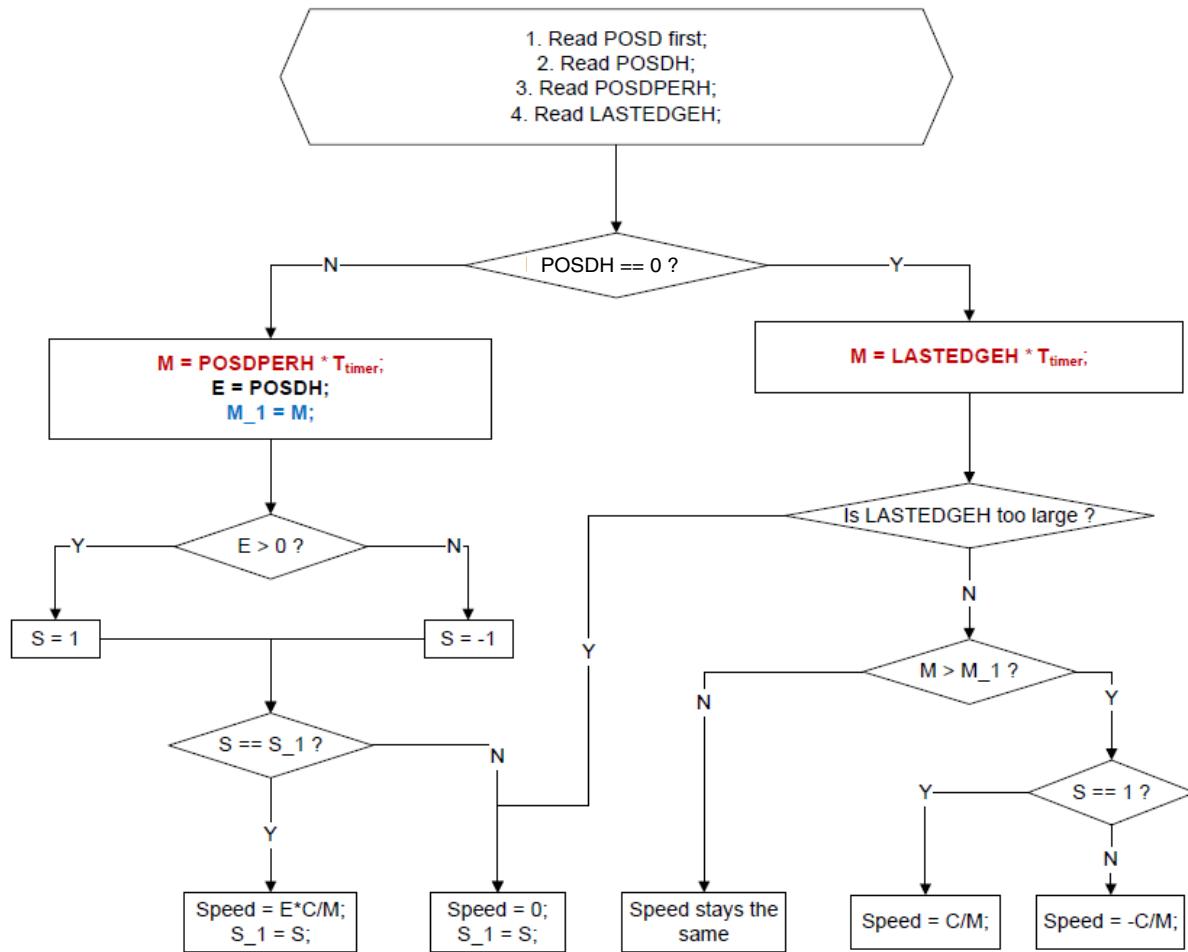

Figure 56-6. Flowchart of speed calculation with method

#### 56.3.4.2 Speed calculation of motor's starting from standstill (Chip is out of reset)

### 56.3.5 Clocks

The IPBus clock is the only clock required by this module in normal operation.

### 56.3.6 Resets

There are no special requirements. This module is reset by any system reset.

### 56.3.7 Interrupts

The following table lists the module interrupts.

Table 56-2. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Description
ipi_int_home	CTRL[HIRQ]	CTRL[HIE]	HOME signal transition interrupt

Table continues on the next page...

**Table 56-2. Interrupt Summary (continued)**

Core Interrupt	Interrupt Flag	Interrupt Enable	Description
ipi_int_index	CTRL[XIRQ]	CTRL[XIE]	INDEX signal transition interrupt or roll-over/under interrupt
	CTRL2[ROIRQ]	CTRL2[ROIE]	
	CTRL2[RUIRQ]	CTRL2[RUIE]	
ipi_int_wdog	CTRL[DIRQ]	CTRL[DIE]	Watchdog timeout interrupt
ipi_int_comp	CTRL[CMPIRQ]	CTRL[CMPIE]	Compare match interrupt

## 56.4 Signal Descriptions

Four external signals are multiplexed to the four pins (PHASEA, PHASEB, INDEX, HOME) of a quad timer module. Two internal signals (TRIGGER, POSMATCH) can be connected to other SoC resources.

**Table 56-3. Signals**

Signal		Description
PHASEA	Phase A Input	<p>The PHASEA input can be connected to one of the phases from a two-phase shaft quad encoder output. PHASEA and PHASEB are used by the quad decoder module to indicate a decoder increment has passed, and to calculate its direction.</p> <ul style="list-style-type: none"> <li>When the quad decoder module is used as a single phase pulse accumulator, PHASEA can also be used as the single input.</li> <li>The PHASEA input can be an input capture channel for one of the timer modules (in the SoC), which can be connected to using a crossbar switch.</li> </ul> <p>Direction for two-phase shaft quad encoder output:</p> <ul style="list-style-type: none"> <li>PHASEA is the leading phase for a shaft rotating in the positive direction.</li> <li>PHASEA is the trailing phase for a shaft rotating in the negative direction.</li> </ul>
PHASEB	Phase B Input	<p>The PHASEB input can be connected to the other phase from a two-phase shaft quad encoder output.</p> <ul style="list-style-type: none"> <li>The PHASEB input can be an input capture channel for one of the timer modules (in the SoC), which can be connected to using a crossbar switch.</li> </ul> <p>Direction for two-phase shaft quad encoder output:</p> <ul style="list-style-type: none"> <li>PHASEB is the trailing phase for a shaft rotating in the positive direction.</li> <li>PHASEB is the leading phase for a shaft rotating in the negative direction.</li> </ul>
INDEX	Index Input	<ul style="list-style-type: none"> <li>Normally connected to the index pulse output of a quad encoder, the INDEX pulse can optionally reset the position counter and the pulse accumulator of the quad decoder module. The INDEX pulse also causes a change of state on the revolution counter. The direction of this state change (increment or decrement) is calculated from the PHASEA and PHASEB inputs.</li> <li>The INDEX input can be an input capture channel for one of the timer modules (in the SoC), which can be connected to using a crossbar switch.</li> </ul>
HOME	Home Switch Input	<p>The HOME input can be used by the quad decoder and the timer module.</p> <ul style="list-style-type: none"> <li>The HOME input can be used to trigger the initialization of the position counters (UPOS and LPOS). Often the HOME signal is connected to a</li> </ul>

*Table continues on the next page...*

Signal		Description
		<p>sensor on the motor or machine, sending notification that it has reached a defined home position.</p> <ul style="list-style-type: none"> <li>The HOME signal can be connected to the timer module (in the SoC) using a crossbar switch.</li> </ul>
TRIGGER	Trigger Input	<p>The TRIGGER input can be used</p> <ul style="list-style-type: none"> <li>to clear the position counters (UPOS and LPOS)</li> <li>to take a snapshot of the POS, REV, and POSD registers</li> <li>to indicate an elapsed time period, by connecting the TRIGGER input signal to a periodic pulse generator or timer</li> </ul>
POSMATCH	Position Match Output	<ul style="list-style-type: none"> <li>To record the time at which the position of the shaft matches a user-defined compare value (COMP), the POSMATCH output can be used to trigger a timer channel.</li> <li>Alternatively, to record the time at which the position information was read, (when the position counters (UPOS and LPOS), revolution counter (REV), or position difference counter (POSD) registers are read) the POSMATCH output can be used to trigger a timer channel.</li> </ul>

## 56.5 Memory Map and Registers

This section describes the module memory map and registers.

### 56.5.1 QDC register descriptions

The address of a register is the sum of a base address and an address offset.

- Base address is defined at the MCU level
- Address offset is defined at the module level

For the base address, see the specific chip documentation. All memory locations base and offsets are given in hex.

#### 56.5.1.1 QDC memory map

QDC1 base address: 403C\_8000h

QDC2 base address: 403C\_C000h

QDC3 base address: 403D\_0000h

QDC4 base address: 403D\_4000h

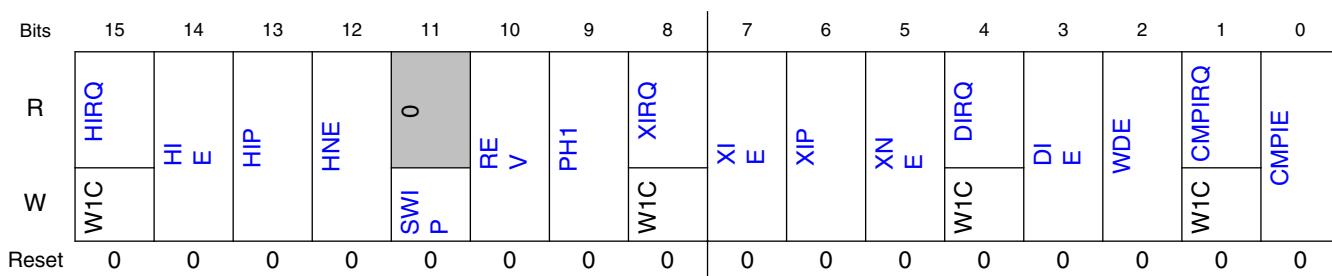

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Register (CTRL)	16	RW	0000h
2h	Input Filter Register (FILT)	16	RW	0000h
4h	Watchdog Timeout Register (WTR)	16	RW	0000h
6h	Position Difference Counter Register (POSD)	16	RW	0000h
8h	Position Difference Hold Register (POSDH)	16	RO	0000h
Ah	Revolution Counter Register (REV)	16	RW	0000h
Ch	Revolution Hold Register (REVH)	16	RO	0000h
Eh	Upper Position Counter Register (UPOS)	16	RW	0000h
10h	Lower Position Counter Register (LPOS)	16	RW	0000h
12h	Upper Position Hold Register (UPOSH)	16	RO	0000h
14h	Lower Position Hold Register (LPOSH)	16	RO	0000h
16h	Upper Initialization Register (UINIT)	16	RW	0000h
18h	Lower Initialization Register (LINIT)	16	RW	0000h
1Ah	Input Monitor Register (IMR)	16	RO	0000h

	<ul style="list-style-type: none"> <li>• INDEX Pulse Interrupt Request will remain set until cleared by software</li> <li>• Write a one to this bit (XIRQ) to clear it</li> </ul> <p>0b - INDEX pulse has not occurred 1b - INDEX pulse has occurred</p>
7 XIE	INDEX Pulse Interrupt Enable Enables/disables INDEX pulse interrupts. 0b - Disabled 1b - Enabled
6 XIP	INDEX Triggered Initialization of Position Counters UPOS and LPOS Enables/disables the position counter to be initialized by the INDEX pulse. 0b - INDEX pulse does not initialize the position counter 1b - INDEX pulse initializes the position counter
5 XNE	Use Negative Edge of INDEX Pulse Selects the positive/negative edge of the INDEX pulse used to initialize the position counter. 0b - Use positive edge of INDEX pulse 1b - Use negative edge of INDEX pulse
4 DIRQ	Watchdog Timeout Interrupt Request Watchdog Timeout Interrupt Request is set when a watchdog timeout interrupt occurs. <ul style="list-style-type: none"> <li>• Watchdog Timeout Interrupt Request will remain set until cleared by software</li> <li>• Write a one to this bit (DIRQ) to clear it</li> <li>• Watchdog Timeout Interrupt Request bit is also cleared when Watchdog Enable (CTRL[WDE]) is disabled (=0)</li> </ul> <p>0b - No Watchdog timeout interrupt has occurred 1b - Watchdog timeout interrupt has occurred</p>
3 DIE	Watchdog Timeout Interrupt Enable Enables/disables watchdog timeout interrupts. 0b - Disabled 1b - Enabled
2 WDE	Watchdog Enable Enables/disables the watchdog timer that is monitoring the PHASEA and PHASEB inputs for motor movement. 0b - Disabled 1b - Enabled
1 CMPIRQ	Compare Interrupt Request Compare Interrupt Request is set when the counter matches the COMP value. <ul style="list-style-type: none"> <li>• Compare Interrupt Request remains set until cleared by software</li> <li>• Write 1 to this bit (CMPIRQ) to clear it</li> </ul> <p>0b - No match has occurred (the counter does not match the COMP value) 1b - COMP match has occurred (the counter matches the COMP value)</p>
0 CMPIE	Compare Interrupt Enable Enables/disables compare interrupt. 0b - Disabled 1b - Enabled

### 56.5.1.3 Input Filter Register (FILT)

#### 56.5.1.3.1 Offset

Register	Offset
FILT	2h

#### 56.5.1.3.2 Function

The Input Filter Register sets the values of the input filter sample period (FILT\_PER), the filter prescaler (FILT\_PRSC) and the input filter sample count (FILT\_CNT).

- The Input Filter prescaler value (FILT\_PRSC) should be set to prescale the IPBus clock. (frequency of FILT clock) = (frequency of IPBus clock) /  $2^{\text{FILT\_PRSC}}$
- The Input Filter Sample Period (FILT\_PER) should be set so that the sampling period is larger than the period of the expected noise. Doing this means that a noise spike will only corrupt one sample.
- The Input Filter Sample Count (FILT\_CNT) should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of  $\text{FILT\_CNT}+3$ .

The values of the Input Filter Sample Period (FILT\_PER) and the Input Filter Sample Count (FILT\_CNT) must also be traded off against the desire for minimal latency in recognizing valid input transitions. Turning on the input filter (setting the Input Filter Sample Period (FILT\_PER) to a non-zero value) introduces a latency of  $((\text{FILT\_CNT}+3)*\text{FILT\_PER})$  FILT clock cycles +2 IPBus clock periods.

The filter latency can be measured:

- Drive the quadrature decoder inputs (PHASEA, PHASEB, INDEX, HOME)
- Monitor the filtered output in the Input Monitor Register (IMR)
- Determine how many IPBus clock cycles that it takes before the output shows up, by using the following equations, where f is FILT\_PER and s is FILT\_CNT.
  - $\text{DELAY} = f * (s+3)(\text{FILT clock cycles}) + 1$  (IPBus clock cycles)(to read the filtered output)
  - $\text{DELAY} = f * (s+3)(\text{FILT clock cycles}) + 2$  (IPBus clock cycles) (to monitor the output in the IMR)

One more additional IPBus clock cycle is needed to read the filtered output, and 2 more IPBus clock cycles are needed to monitor the filtered output in the IMR. The sample rate is set when it reaches the number f. The following examples use the preceding equations:

- Example: when  $f = 0$ , the filter is bypassed:  $\text{DELAY} = 1$  or  $2$  clock cycles.
- Example: when  $f = 5$  and  $s = 2$ :  $\text{DELAY} = 5 * (2+3)\text{FILT}$  clock cycles + (1 or 2)IPBus clock cycles

### 56.5.1.3.3 Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FILT_PRSC				0	FILT_CNT			FILT_PER

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### 56.5.1.3.4 Fields

Field	Function
15-13 FILT_PRSC	prescaler divide IPbus clock to FILT clk  The Prescaler field is used to prescale the IPbus clock to FILT clock. The IPbus clock is prescaled by a value of $2^{\text{FILT\_PRSC}}$ which means that the prescaler logic can divide the clock by a minimum of 1 and a maximum of 128. So FILTER can filt lower freq noise.
12-11 —	Reserved
10-8 FILT_CNT	Input Filter Sample Count  The Input Filter Sample Count represents the number of consecutive samples that must agree, before the input filter accepts an input transition. <ul style="list-style-type: none"> <li>• A value of 0x0 represents 3 samples</li> <li>• A value of 0x7 represents 10 samples</li> </ul> The value of the Input Filter Sample Count (FILT_CNT) affects the input latency.
7-0 FILT_PER	Input Filter Sample Period  The Input Filter Sample Period represents the sampling period (in IPBus clock cycles) of the decoder input signals. Each input is sampled multiple times at the rate specified by the Input Filter Sample Period. <ul style="list-style-type: none"> <li>• If FILT_PER is 0x00 (default), then the input filter is bypassed. Bypassing the digital filter enables the position/position difference counters to operate with count rates up to the IPBus frequency.</li> <li>• The value of the Input Filter Sample Period (FILT_PER) affects the input latency.</li> <li>• When changing the Input Filter Sample Period (FILT_PER) from a non-zero value to another non-zero value, write a value of 0 first, to clear the filter.</li> </ul>

### 56.5.1.4 Watchdog Timeout Register (WTR)

### 56.5.1.4.1 Offset

Register	Offset
WTR	4h

### 56.5.1.4.2 Function

The Watchdog Timeout Register stores the timeout count for the quadrature decoder module watchdog timer. This quadrature decoder module watchdog timer is separate from any other watchdog timer(s) that may also be in the device.

### 56.5.1.4.3 Diagram

### 56.5.1.4.4 Fields

Field	Function
15-0	WDOG
WDOG	WDOG[15:0] is a binary representation of the number of clock cycles, plus one clock cycle that the watchdog timer counts before timing out (and optionally generating an interrupt).

## 56.5.1.5 Position Difference Counter Register (POSD)

### 56.5.1.5.1 Offset

Register	Offset
POSD	6h

### 56.5.1.5.2 Function

The Position Difference Counter Register contains the position change in value occurring between each read of the Position Register. The value of the Position Difference Counter Register can be used to calculate velocity.

- The 16-bit Position Difference Counter computes up or down on every count pulse.
- This Position Difference Counter acts as a differentiator, whose count value is proportional to the change in position since the last time that the Position Counter was read.
- When the Position Registers (UPOS or LPOS), the Position Difference Counter (POSD), or the Revolution Counter (REV) is read, the Position Difference Counter's contents are copied into the Position Difference Hold Register (POSDH) and the Position Difference Counter is cleared.

### 56.5.1.5.3 Diagram

INIT	The value to be used to initialize the lower half of the position counter (LPOS)

## 56.5.1.15 Input Monitor Register (IMR)

### 56.5.1.15.1 Offset

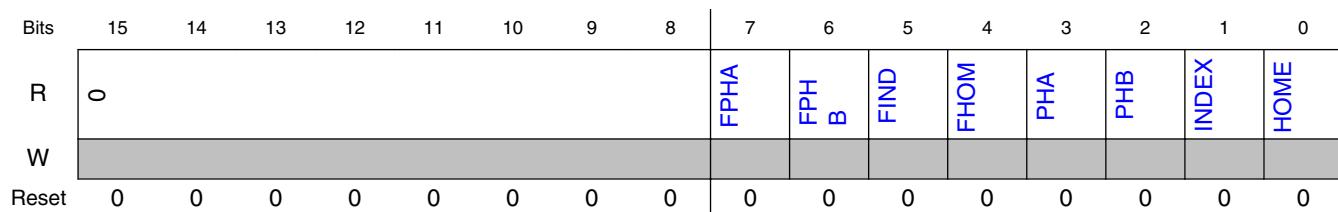

Register	Offset
IMR	1Ah

### 56.5.1.15.2 Function

The Input Monitor Register contains the values of the raw and filtered PHASEA, PHASEB, INDEX, and HOME input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME input signals:

- If these input pins are connected to a pull-up, then bits 0–7 of the IMR are all ones.
- If these input pins are connected to a pull-down device, then bits 0–7 of the Input Monitor Register (IMR) are all zeros.

## 56.5.1.16 Test Register (TST)

### 56.5.1.16.1 Offset

Register	Offset
TST	1Ch

### 56.5.1.16.2 Function

The Test Register controls and sets the frequency of a quadrature signal generator; it provides a quadrature test signal to the inputs of the quadrature decoder module.

- The TEST\_COUNT value is counted down to zero when the test module is enabled (TEN = 1) and the count is enabled (TCE = 1).
- Each count value of one represents a single quadrature cycle interpreted as a count of one by the position counter (UPOS and LPOS) if it is enabled (TEN = 1, TCE = 1).
- Repeated writing of new values to TEST\_COUNT can cause an extra phase transition and therefore an extra count by the Position Counter.
- The period field determines the length (in IPBus clock cycles) of each quadrature cycle phase.

The Test Register is a factory test feature; however, it can also be useful in customer software development and testing.

### 57.2 Overview

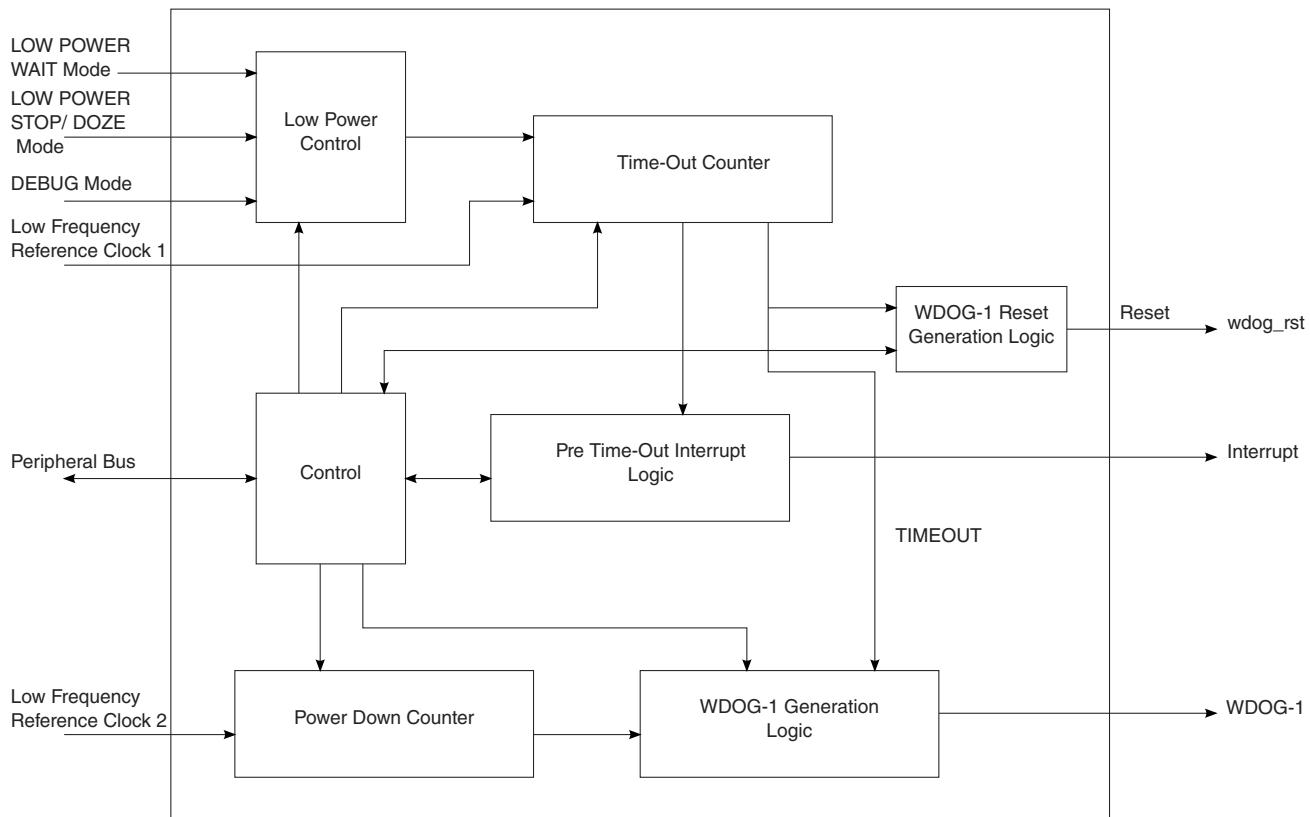

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG1 asserts the internal system reset signal, WDOG\_RESET\_B\_DEB to the System Reset Controller (SRC); and WDOG2 asserts interrupt to SNVS, to report the security violation condition.

There is also a provision for WDOG(ipp\_wdog) signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter

timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG(ipp\_wdog) signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are shown in [Flow Diagrams](#).

**Figure 57-1. WDOG Diagram**

### NOTE

WDOG-1 means WDOG\_B when it presents on a PAD.

## 57.2.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG\_RESET\_B\_DEB reset signal.
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes

- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout
- The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG\_B (ipp\_wdog) signal low
  - Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

## 57.3 External signals

**Table 57-2. WDOG External Signals**

Signal	Description	Direction
WDOG1_ANY	Global WDOG signal. It is AND of WDOG1_B signal and WDOG2_B signal.	O
WDOG1_B	This signal can be routed to external pin of the chip. It is asserted by a software request (set the WDA bit), by power down counter and timeout counter expiration.	O
WDOG1_RST_B_DEB	This signal is a reset source for the chip.	O
WDOG2_B	This signal can be routed to external pin of the chip. It is asserted by a software request (set the WDA bit), by power down counter and timeout counter expiration.	O
WDOG2_RST_B_DEB	This signal asserts interrupt to SNVS to report the security violation condition.	O

See more detailed information in the Pin MUX chapter.

## 57.4 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The following table describes the clock sources for WDOG. Please see for clock setting, configuration and gating information.

**Table 57-3. WDOG Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	IP Global functional clock. All functionality inside the WDOG module is synchronized to this clock.
ipg_clk_s	ipg_clk_root	IP slave bus clock. This clock is synchronized to ipg_clk and is only used for register read/write operations.
ipg_clk_32k	ckil_sync_clk_root	Low frequency (32.768 kHz) clock that continues to run in low-power mode. It is assumed that the Clock Controller will provide this clock signal synchronized to ipg_clk in the normal mode, and switch to a non-synchronized signal in low-power mode when the ipg_clk is off.
ipg_async_ckil_clk	anatop_xtal32k_clk	This clock is used by clocking the power down counter.

## 57.5 Watchdog mechanism and system integration

The WDOG1 module and the WDOG2 (TZ) module are disabled by default (after reset). WDOG1 will be configured during boot while WDOG2 is dedicated for secure world purposes and will be activated by TZ software if required. The TZ watchdog (WDOG2) module protects against TZ starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode. TZ starvation is a situation where the normal OS prevents switching to the TZ mode. Such a situation is undesirable as it can compromise the system's security.

Once the TZ WDOG module is activated, it must be serviced by TZ on a periodic basis. If servicing does not take place, the timer times out. Upon a timeout, the TZ WDOG asserts a TZ-mapped interrupt that forces switching to the TZ mode. If it is still not serviced, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or de-activated by normal mode software.

The WDOG modules operate as follows:

- If servicing does not take place, the timer times out and the wdog\_RST\_B signal is activated (low)
- Interrupt can be generated before the counter actually times out
- The wdog\_RST\_B signal can be activated by software
- There is a power-down counter which gets enabled out of any reset. This counter has a fixed timeout period of 16 seconds upon which it will assert the ipg\_wdog\_B signal.

## 57.6 Functional description

This section provides a complete functional description of the block.

## 57.6.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the [Watchdog Control \(WCR\)](#). The WDOG must be enabled by setting the WDE bit of [Watchdog Control \(WCR\)](#) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the [WDOG](#) outputs a system reset signal, [WDOG\\_RESET\\_B\\_DEB](#) and asserts [WDOG\\_B](#) ([ipp\\_wdog](#)) (WDT bit should be set in [Watchdog Control \(WCR\)](#)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of [WDOG\\_WCR](#)) if a service routine (see [Servicing WDOG to reload the counter](#)) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the [Watchdog Service \(WSR\)](#), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the [Watchdog Control \(WCR\)](#) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in [Flow Diagrams](#).

### NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

### 57.6.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x\_5555 followed by 0x\_AAAA to the [Watchdog Service \(WSR\)](#). Any number of instructions can be executed between the two writes. If the [WDOG\\_WSR](#) is not loaded with 0x\_5555 prior to writing 0x\_AAAA to the [WDOG\\_WSR](#), the counter is not reloaded. If any value other than 0x\_AAAA is written to the [WDOG\\_WSR](#) after 0x\_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of [Watchdog Control \(WCR\)](#). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

## 57.6.2 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of [Watchdog Interrupt Control \(WICR\)](#). It can vary between 0 and 127.5 seconds. If the WDOG is serviced ([Servicing WDOG to reload the counter](#)) before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control \(WCR\)](#) and the interrupt will not be triggered.

## 57.6.3 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG\_B ([ipp\\_wdog](#)) signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of [Watchdog Miscellaneous Control \(WMCR\)](#) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

## 57.6.4 Low power modes

### 57.6.4.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the [Watchdog Control \(WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.

### 57.6.4.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the [Watchdog Control \(WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock i.e *ipg\_clk\_32k* clock (32.768 kHz frequency clock). If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

#### NOTE

The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle.

For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

### 57.6.5 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the [Watchdog Control \(WCR\)](#), the WDOG timer operation is suspended in debug mode. If the WDBG bit is set and the debug mode (*ipg\_debug* signal assertion) is entered, WDOG timer operation is suspended after two low frequency reference (*ipg\_clk\_32k*) clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of [Watchdog Control \(WCR\)](#) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

#### NOTE

If the WDE bit of [Watchdog Control \(WCR\)](#) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

### 57.6.6 Operations

### 57.6.6.1 Watchdog reset generation

The WDOG generated reset signal WDOG\_RESET\_B\_DEB is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the [Watchdog Control \(WCR\)](#).
- WDOG timeout. See [Timeout event](#).

The `wdog_rst` will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between.

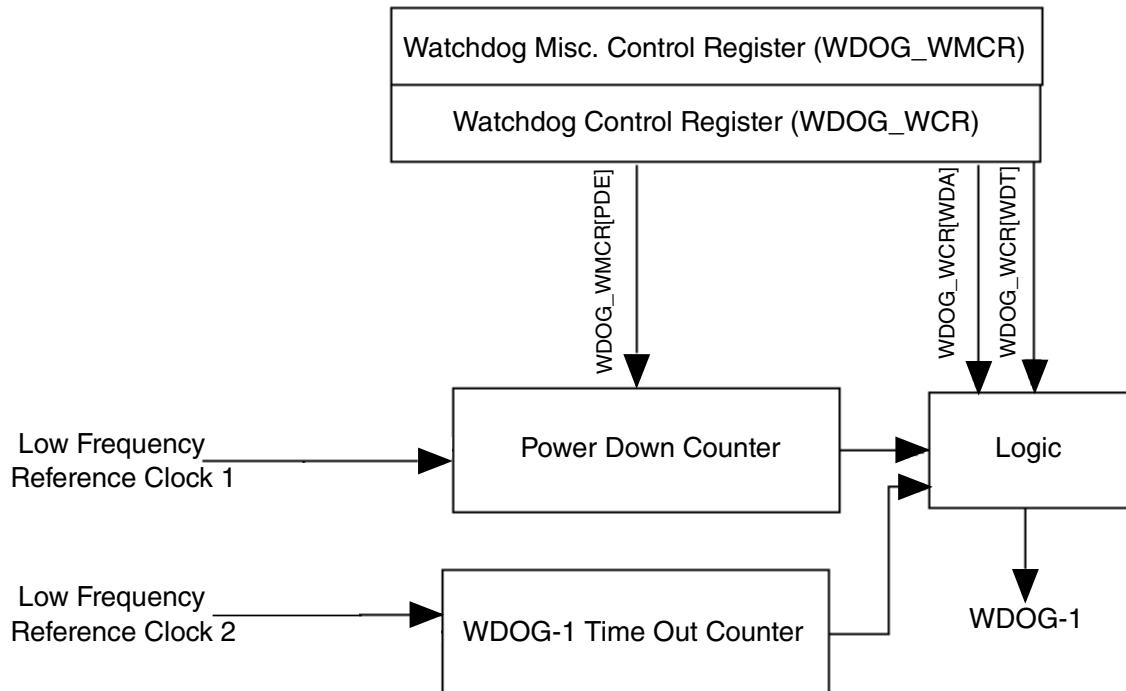

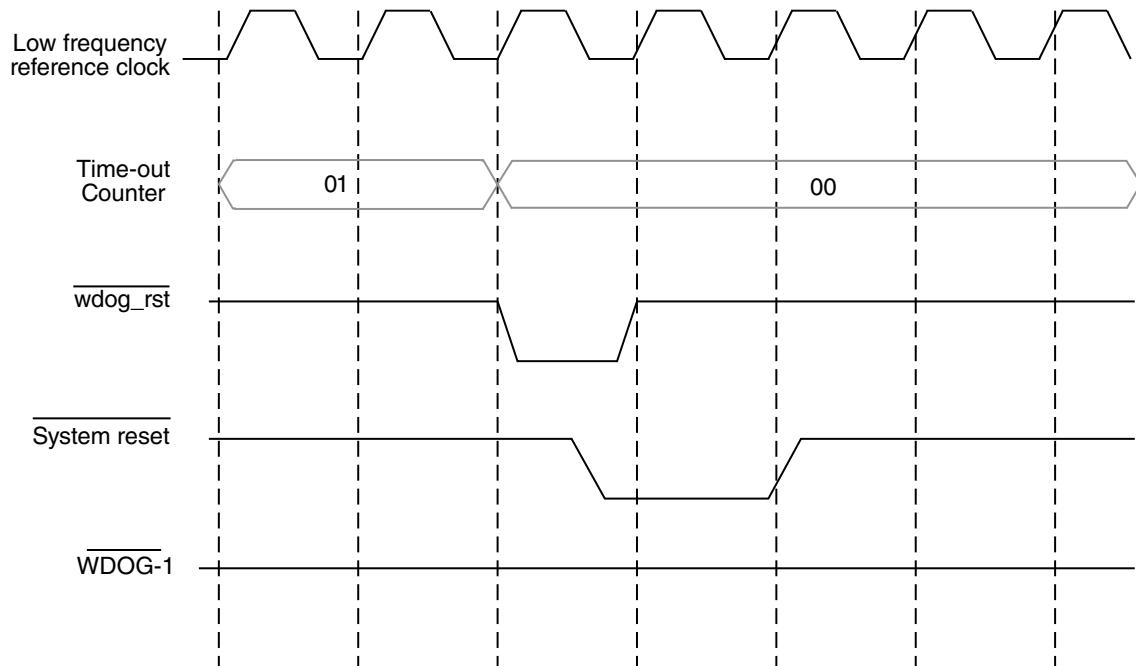

[Figure 57-3](#) shows the timing diagram of this signal due to a timeout condition.

### 57.6.6.2 WDOG\_B generation

The WDOG asserts WDOG\_B in the following scenarios:

- Software write to WDA bit of [Watchdog Control \(WCR\)](#). WDOG\_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of [Watchdog Control \(WCR\)](#) must be set for this scenario. A description of the timeout condition can be found in the [Timeout event](#). WDOG\_B (ipp\_wdog) signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). [Figure 57-4](#) shows the timing diagram of WDOG\_B (ipp\_wdog) due to timeout condition.
- WDOG power-down counter timeout, PDE bit of [Watchdog Miscellaneous Control \(WMCR\)](#) should not be cleared for this scenario. A description of this counter can be found in the [Power-down counter event](#). WDOG\_B (ipp\_wdog) signal remains asserted for one clock cycle of low frequency reference clock (`ipg_clk_32k`).

[Figure 57-2](#) shows the scenarios under which WDOG\_B(`ipp_wdog`) gets asserted.

**Figure 57-2. WDOG\_B (ipp\_wdog) generation****Figure 57-3. WDOG timeout condition/WDT bit is not set**

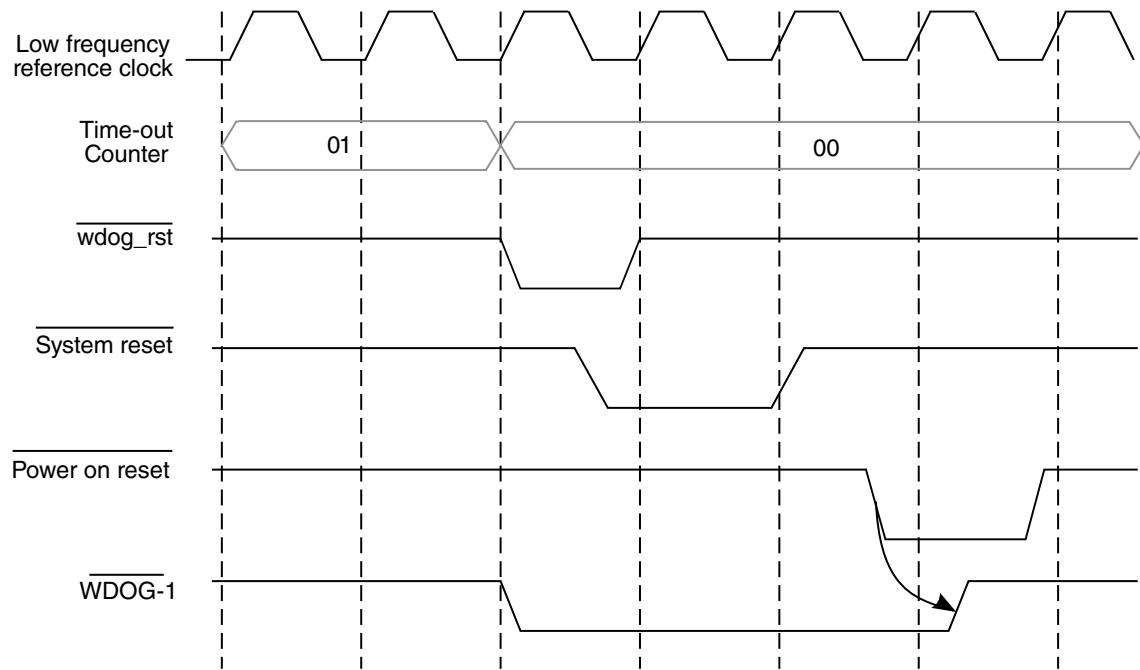

Figure 57-4. WDOG timeout condition/WDT bit is set

## 57.6.7 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

## 57.6.8 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in [Watchdog Interrupt Control \(WICR\)](#) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of [Watchdog Interrupt Control \(WICR\)](#). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in [Watchdog Interrupt Control \(WICR\)](#) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control \(WCR\)](#) and interrupt would not be triggered.

## 57.6.9 Flow Diagrams

A flow diagram of WDOG operation is shown below.

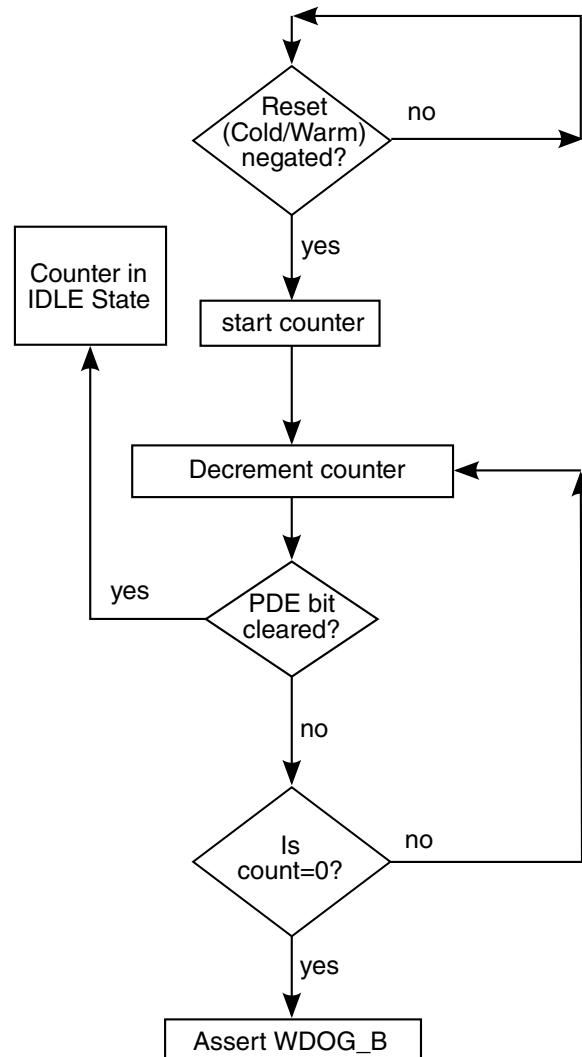

Figure 57-5. Power-Down Counter Flow Diagram

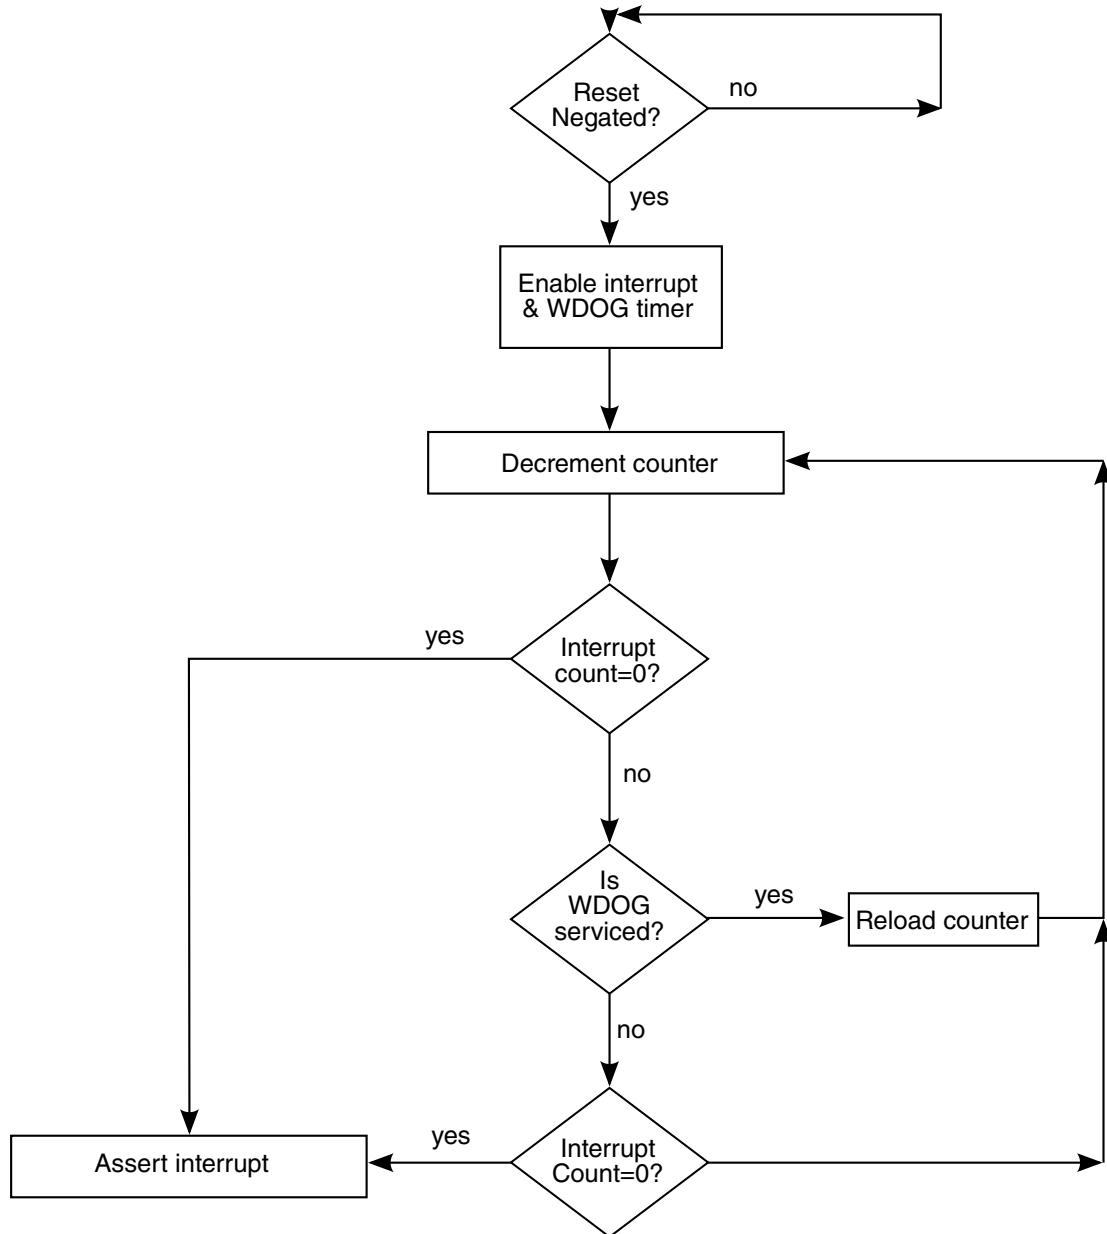

Figure 57-6. Interrupt Generation Flow Diagram

## 57.7 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of [Watchdog Miscellaneous Control \(WMCR\)](#) should be cleared to disable the power down counter.

- WT field of [Watchdog Control \(WCR\)](#) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of [Watchdog Control \(WCR\)](#) so that the timeout counter loads the WT field value of [Watchdog Control \(WCR\)](#) and starts counting.

## 57.8 WDOG Memory Map/Register Definition

### 57.8.1 WDOG Register Descriptions

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed, the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

#### 57.8.1.1 WDOG Memory Map

WDOG1 base address: 400B\_8000h.

WDOG2 base address: 400D\_0000h.

#### 57.8.1.2 Watchdog Control (WCR)

### 57.8.1.2.1 Address

Register	Offset
WCR	0h

### 57.8.1.2.2 Function

The Watchdog Control Register (WDOG\_WCR) controls the WDOG operation.

- WDZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.
- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/cleared due to any system reset.

### 57.8.1.2.4 Fields

Field	Function
15-8 WT	<p>Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter.</p> <p><b>NOTE:</b> The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see <a href="#">Timeout event</a>.</p> <ul style="list-style-type: none"> <li>00000000b - - 0.5 Seconds (Default).</li> <li>00000001b - - 1.0 Seconds.</li> <li>00000010b - - 1.5 Seconds.</li> <li>00000011b - - 2.0 Seconds.</li> <li>11111111b - - 128 Seconds.</li> </ul>

Table continues on the next page...

Field	Function
7 WDW	WDW Watchdog Disable for Wait. This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit. 0b - Continue WDOG timer operation (Default). 1b - Suspend WDOG timer operation.
6 SRE	software reset extension, an option way to generate software reset adopt a new way to generate a more robust software reset. This bit can be set/clear with IP bus and will be reset with power-on reset . 0b - using original way to generate software reset (default) 1b - using new way to generate software reset.
5 WDA	WDA WDOG_B assertion. Controls the software assertion of the WDOG_B signal. 0b - Assert WDOG_B output. 1b - No effect on system (Default).
4 SRS	SRS Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal WDOG_RESET_B_DEB . This bit automatically resets to "1" after it has been asserted to "0". <b>NOTE:</b> This bit does not generate the software reset to the block. 0b - Assert system reset signal. 1b - No effect on the system (Default).
3 WDT	WDT WDOG_B Time-out assertion. Determines if the WDOG_B gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit. <b>NOTE:</b> There is no effect on WDOG_RESET_B_DEB (WDOG Reset) upon writing on this bit. WDOG_B gets asserted along with WDOG_RESET_B_DEB if this bit is set. 0b - No effect on WDOG_B (Default). 1b - Assert WDOG_B upon a Watchdog Time-out event.
2 WDE	WDE Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set. <b>NOTE:</b> This bit can be set/reset in debug mode (exception). 0b - Disable the Watchdog (Default). 1b - Enable the Watchdog.
1 WDBG	WDBG Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only. 0b - Continue WDOG timer operation (Default). 1b - Suspend the watchdog timer.
0 WDZST	WDZST Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only. <b>NOTE:</b> The WDOG can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode). 0b - Continue timer operation (Default). 1b - Suspend the watchdog timer.

### 57.8.1.3 Watchdog Service (WSR)

#### 57.8.1.3.1 Address

Register	Offset
WSR	2h

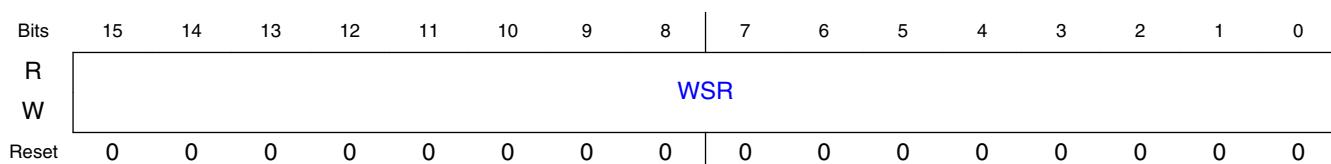

#### 57.8.1.3.2 Function

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

#### NOTE

Executing the service sequence will reload the WDOG timeout counter.

#### 57.8.1.3.3 Diagram

#### 57.8.1.3.4 Fields

Field	Function
15-0 WSR	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows:  01010101010101b - Write to the Watchdog Service Register (WDOG_WSR). 10101010101010b - Write to the Watchdog Service Register (WDOG_WSR).

### 57.8.1.4 Watchdog Reset Status (WRSR)

### 57.8.1.4.1 Address

Register	Offset
WRSR	4h

### 57.8.1.4.2 Function

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error.

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

## RTWDOG (WDOG3)

### 58.1 Chip-specific RTWDOG information

Table 58-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

The clock source options for this module includes the following items, selected via CS[CLK].

- 00b: bus clock (BUS\_CLK)
- 01b: Low-Power Oscillator clock (LPO\_CLK)
- 10b: internal clock (INTCLK)
- 11b: external clock (ERCLK)

#### NOTE

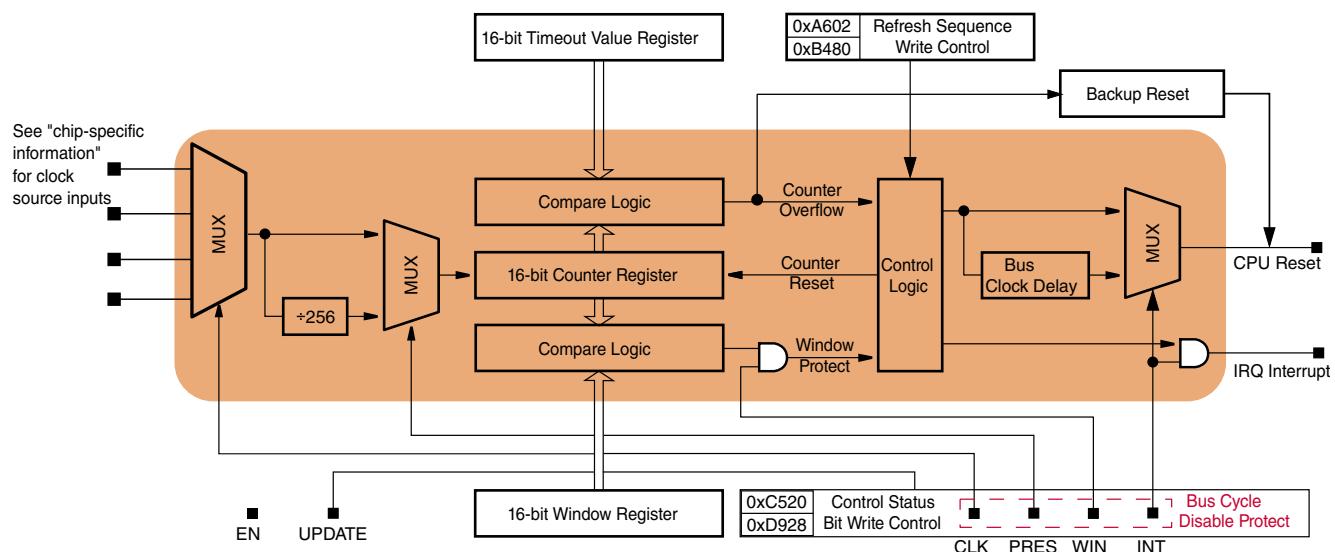

- On this device, both LPO clock and INTCLK are 32 KHz clock generated by 32 KHz XTAL, which could be automatically switched to 32 KHz RCOSC upon XTAL clock loss. ERCLK is 1 MHz RCOSC clock generated by ANATOP.

## 58.2 Overview

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

### 58.2.1 Block diagram

The following figure shows a block diagram of the WDOG module.

**Figure 58-1. WDOG block diagram**

### 58.2.2 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequence for counter refresh

- Refresh sequence of writing 0xA602 and then 0xB480
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset.
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
  - Forced reset occurs 128 bus clocks after the interrupt vector fetch.
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.
- Robust write sequence for unlocking write-once configuration bits
  - Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
  - Software must make updates within 128 bus clocks after unlocking and before WDOG closing unlock window.

## 58.3 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

### 58.3.1 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

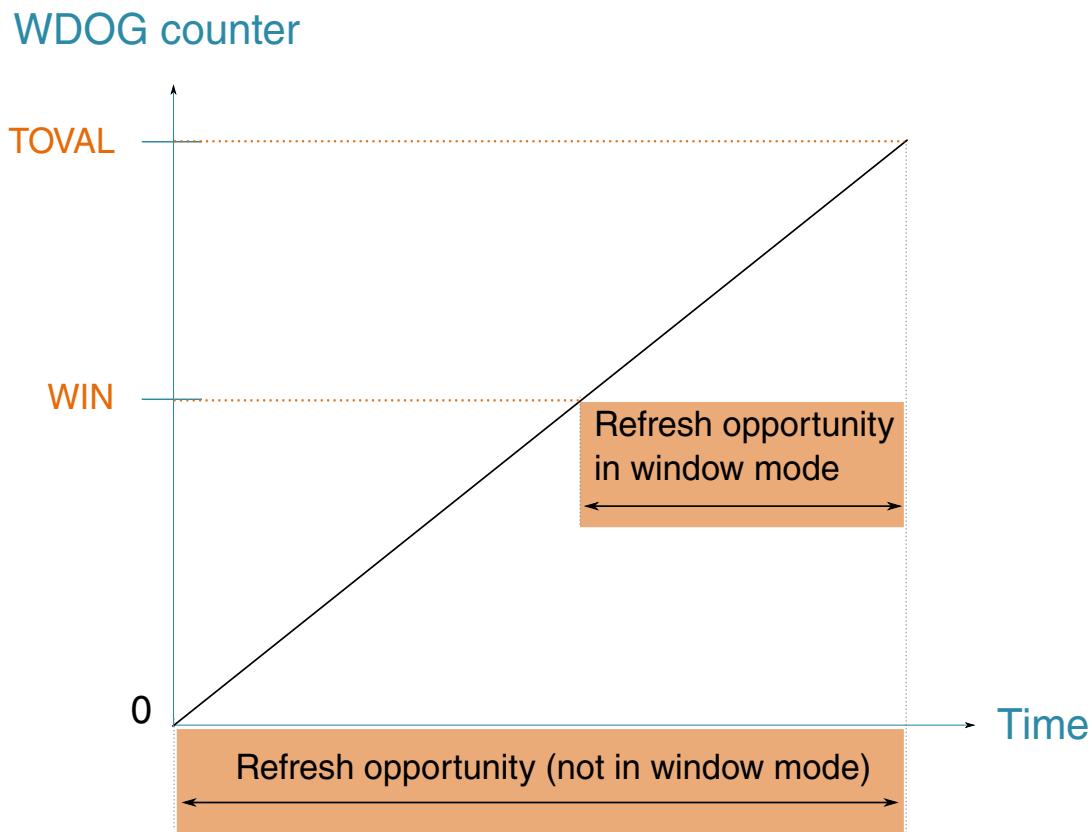

Figure 58-2. Refresh opportunity for the Watchdog counter

### 58.3.1.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

### 58.3.1.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes (0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80) if WDOG\_CS[CMD32EN] is 0;
- one 32-bit write (0xB480\_A602) if WDOG\_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

#### Note

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

### 58.3.2 Configuring the Watchdog

#### 58.3.2.1 Configuring the Watchdog Once

All watchdog control bits, timeout value, and window value are write-once after reset. This means that after a write has occurred they cannot be changed unless a reset occurs. This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

#### 58.3.2.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

### 58.3.2.2.1 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 within 16 bus clocks at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 128 bus clocks; otherwise, the watchdog closes the unlock window.

#### NOTE

Due to the 128 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

The example codes can be found at end of this chapter.

### 58.3.3 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode**, set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode**, set CS[WAIT].
- **For Stop mode**, set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

#### NOTE

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

### 58.3.4 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

#### 58.3.4.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

**NOTE**

CS[TST] is cleared by a POR only and not affected by other resets.

### 58.3.4.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

### 58.3.5 Clock source

The watchdog counter has the clock source options selected by programming CS[CLK]. See the "chip-specific information" section for available clock inputs and the default option for this device.

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see [Backup reset](#).

**NOTE**

The *default* clock source of WDOG should be enabled after its functional reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

**Table 58-2. Watchdog timeout availability**

Reference clock	Prescaler	Watchdog time-out availability
REF_CLK	Pass through	1xRCP to 65535xRCP <sup>1</sup>
	Enable	256xRCP to 16776960xRCP

1. RCP means Reference Clock Period.

**NOTE**

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period ( 128 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

**58.3.6 Backup reset****NOTE**

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

**58.3.7 Using interrupts to delay resets**

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay before forcing a reset.

## 58.4 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

### NOTE

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

### NOTE

When Chip startup from BOOT ROM then jump to flash, the watchdog would be disabled in the beginning of bootloader, and enabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG\_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

### 58.4.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG\_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

### 58.4.2 Disable Watchdog after Reset

All of watchdog registers are unlocked by reset. Therefore, unlock sequence is unnecessary, but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS [ULK]); // waiting for lock
while(~WDOG_CS [RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

### 58.4.3 Configure Watchdog

The watchdog can be configured once by setting the WDOG\_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG\_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

#### *Configure once*

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0); //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

#### *Configure for reconfigurable*

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0); //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

### 58.4.4 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

## 58.5 Memory map and register definition

### 58.5.1 WDOG register descriptions

### 58.5.1.1 WDOG memory map

RTWDOG base address: 400B\_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Watchdog Control and Status Register (CS)	32	RW	0000_2980h
4h	Watchdog Counter Register (CNT)	32	RW	0000_0000h
8h	Watchdog Timeout Value Register (TOVAL)	32	RW	0000_0400h
Ch	Watchdog Window Register (WIN)	32	RW	0000_0000h

### 58.5.1.2 Watchdog Control and Status Register (CS)

#### 58.5.1.2.1 Offset

Register	Offset
CS	0h

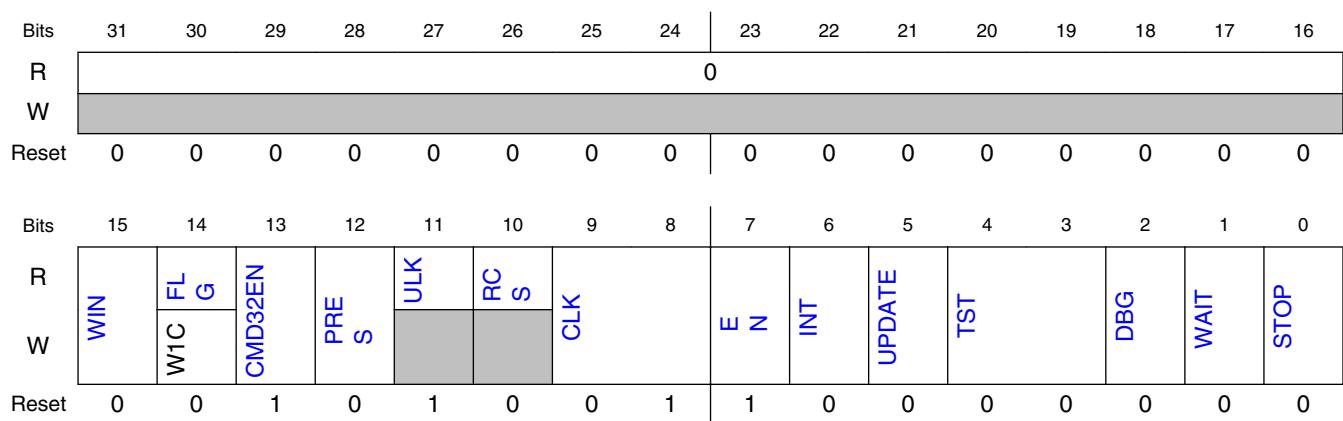

#### 58.5.1.2.2 Function

This section describes the function of Watchdog Control and Status Register.

#### NOTE

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

#### 58.5.1.2.3 Diagram

### 58.5.1.2.4 Fields

Field	Function
31-16 —	Reserved
15 WIN	Watchdog Window  This write-once bit enables window mode. See the <a href="#">Window mode</a> section. 0b - Window mode disabled. 1b - Window mode enabled.
14 FLG	Watchdog Interrupt Flag  This bit is an interrupt indicator when INT is set in control and status register 1. Write 1 to clear it. 0b - No interrupt occurred. 1b - An interrupt occurred.
13 CMD32EN	Enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh/unlock command write words  This is write-once field, and the user needs to unlock WDOG after writing this field for reconfiguration. 0b - Disables support for 32-bit refresh/unlock command write words. Only 16-bit or 8-bit is supported. 1b - Enables support for 32-bit refresh/unlock command write words. 16-bit or 8-bit is NOT supported.
12 PRES	Watchdog prescaler  This write-once bit enables a fixed 256 pre-scaling of watchdog counter reference clock. (The block diagram shows this clock divider option.) 0b - 256 prescaler disabled. 1b - 256 prescaler enabled.
11 ULK	Unlock status  This read-only bit indicates whether WDOG is unlocked or not. 0b - WDOG is locked. 1b - WDOG is unlocked.
10 RCS	Reconfiguration Success  This read-only bit indicates whether the reconfiguration is successful or not. Default reset value is 0.This bit is set when new configuration takes effect, and is cleared by successful unlock command. 0b - Reconfiguring WDOG. 1b - Reconfiguration is successful.
9-8 CLK	Watchdog Clock  This write-once field indicates the clock source that feeds the watchdog counter. See the "chip-specific information" section.
7 EN	Watchdog Enable  This write-once bit enables the watchdog counter to start counting. 0b - Watchdog disabled. 1b - Watchdog enabled.
6 INT	Watchdog Interrupt  This write-once bit configures the watchdog to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to the watchdog), before forcing a reset. After the interrupt vector fetch (which comes after the reset-triggering event), the reset occurs after a delay of 128 bus clocks. 0b - Watchdog interrupts are disabled. Watchdog resets are not delayed.

Table continues on the next page...

## Memory map and register definition

Field	Function
	1b - Watchdog interrupts are enabled. Watchdog resets are delayed by 128 bus clocks from the interrupt vector fetch.
5 UPDATE	<p>Allow updates</p> <p>This write-once bit allows software to reconfigure the watchdog without a reset.</p> <p>0b - Updates not allowed. After the initial configuration, the watchdog cannot be later modified without forcing a reset.</p> <p>1b - Updates allowed. Software can modify the watchdog configuration registers within 128 bus clocks after performing the unlock write sequence.</p>
4-3 TST	<p>Watchdog Test</p> <p>Enables the fast test mode. The test mode allows software to exercise all bits of the counter to demonstrate that the watchdog is functioning properly. See the <a href="#">Fast testing of the watchdog</a> section.</p> <p>This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field.</p> <p>00b - Watchdog test mode disabled.</p> <p>01b - Watchdog user mode enabled. (Watchdog test mode disabled.) After testing the watchdog, software should use this setting to indicate that the watchdog is functioning normally in user mode.</p> <p>10b - Watchdog test mode enabled, only the low byte is used. CNT[CNTLOW] is compared with TOVAL[TOVALLOW].</p> <p>11b - Watchdog test mode enabled, only the high byte is used. CNT[CNTHIGH] is compared with TOVAL[TOVALHIGH].</p>

### 58.5.1.3 Watchdog Counter Register (CNT)

#### 58.5.1.3.1 Offset

Register	Offset
CNT	4h

#### 58.5.1.3.2 Function

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

#### NOTE

All other writes to this register are illegal and force a reset.

#### 58.5.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-16 —	Reserved
15-8 CNTHIGH	High byte of the Watchdog Counter
7-0 CNTLOW	Low byte of the Watchdog Counter

#### 58.5.1.4 Watchdog Timeout Value Register (TOVAL)

### 58.5.1.4.1 Offset

Register	Offset
TOVAL	8h

### 58.5.1.4.2 Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

#### NOTE

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

### 58.5.1.4.3 Diagram

	Low Power Clock Source	<a href="#">Clock Control Module (CCM)</a> <a href="#">Low Power Clock Source (lpo_clk[3:0])</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

#### NOTE

- lpo\_clk[0] is 32 kHz clock generated by 32 kHz XTAL, which could be automatically switched to 32 kHz RCOSC upon XTAL clock loss;
- lpo\_clk[1] is 1 MHz RCOSC clock generated by ANATOP;
- lpo\_clk[3:2] are not used on this device.

### 59.2 Overview

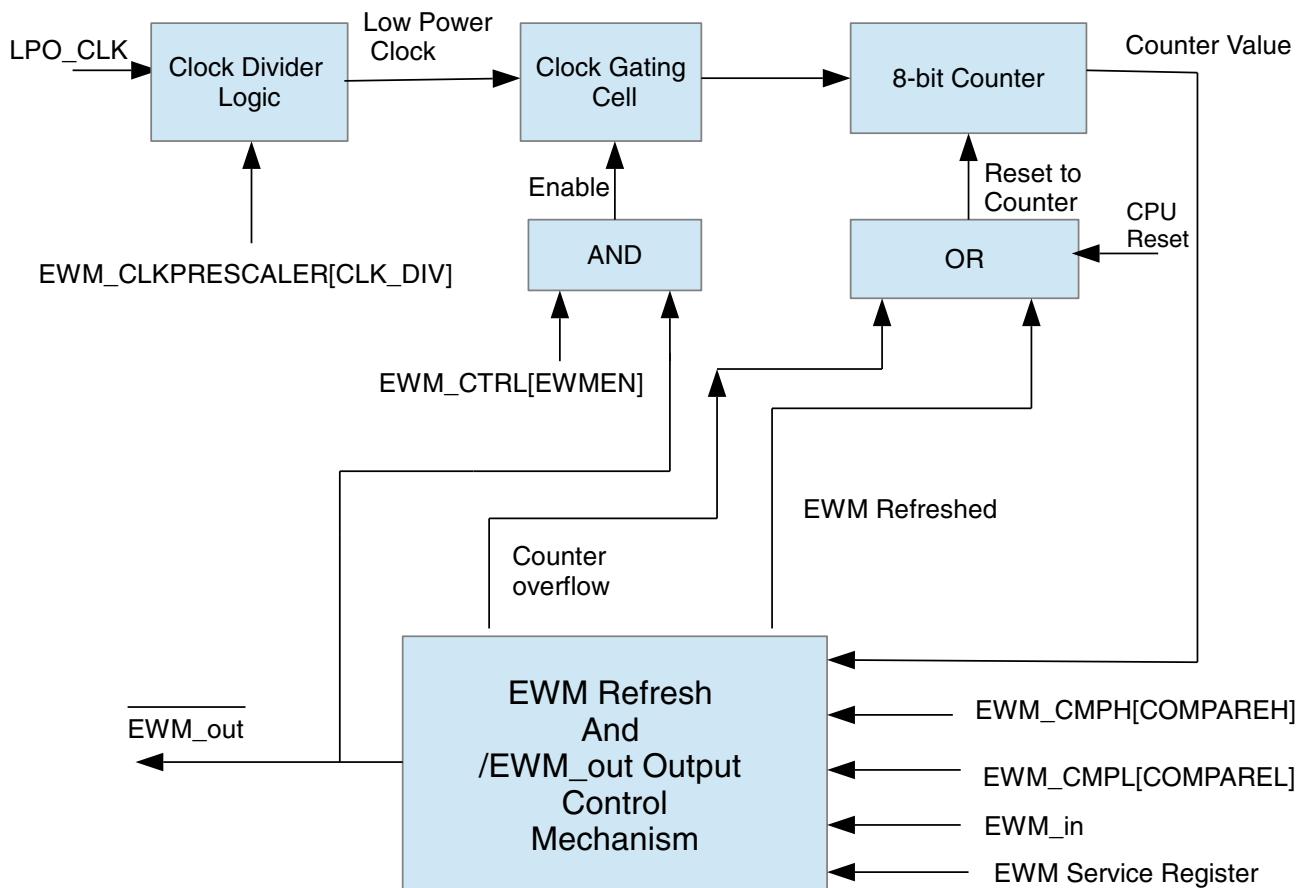

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally asserts the RESET\_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM\_OUT\_b signal that when asserted resets or places an external circuit into a safe mode. The EWM\_OUT\_b signal is asserted upon the EWM counter time-out. An optional external input EWM\_in is provided to allow additional control of the assertion of EWM\_OUT\_b signal.

## 59.2.1 Block Diagram

This figure shows the EWM block diagram.

**Figure 59-1. EWM Block Diagram**

## 59.2.2 Features

Features of EWM module include:

- Independent LPO\_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO\_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of EWM\_OUT\_b.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 63 peripheral bus clock cycles.
- One output port, EWM\_OUT\_b, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM\_in, allows an external circuit to control the assertion of the EWM\_OUT\_b signal.

## 59.3 Functional Description

The following sections describe functional details of the EWM module.

### NOTE

When the BUS\_CLK is lost, then EWM module doesn't generate the EWM\_OUT\_b signal and no refresh operation is possible

### 59.3.1 Modes of Operation

This section describes the module's operating modes.

### 59.3.1.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 63 peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

### 59.3.1.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

### 59.3.1.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

## 59.3.2 The EWM\_OUT\_b Signal

The EWM\_OUT\_b is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM\_OUT\_b could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM\_OUT\_b signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM\_OUT\_b signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM\_in pin is enabled and EWM\_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM\_OUT\_b pin)

The EWM\_OUT\_b is asserted after any reset by the virtue of the external pull-down mechanism on the EWM\_OUT\_b signal. Then, to deassert the EWM\_OUT\_b signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM\_OUT\_b signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM\_OUT\_b signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

### **Note**

EWM\_OUT\_b pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

### **59.3.3 EWM\_OUT\_b pin state in low power modes**

During Wait, Stop and Power Down modes the EWM\_OUT\_b pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

### 59.3.4 The EWM\_in Signal

The EWM\_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM\_OUT\_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM\_OUT\_b signal that controls the gating circuit.

The EWM\_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM\_in functionality (setting the CTRL[INEN] bit), the EWM\_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM\_OUT\_b stays in the deasserted state; otherwise, the EWM\_OUT\_b output signal is asserted.

#### Note

The user must update the CMPL and CMPH registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM\_in pin is deasserted.

### 59.3.5 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

### 59.3.6 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM\_OUT\_b is asserted.

### 59.3.7 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

**Table 59-2. EWM Refresh Mechanisms**

Condition	Mechanism
An EWM refresh action completes when: CMPL < Counter < CMPH.	The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_b output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state.
An EWM refresh action completes when Counter < CMPL	The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.
Counter value reaches CMPH prior to completion of EWM refresh action.	Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.

### 59.3.8 EWM Interrupt

When EWM\_OUT\_b is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect EWM\_OUT\_b. The EWM\_OUT\_b signal can be deasserted only by forcing a system reset.

### 59.3.9 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

### 59.3.10 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK\_DIV]. This divided clock is used to run the EWM counter.

**NOTE**

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

## 59.4 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

**NOTE**

All active-low signals are now represented with the suffix "\_b" throughout the chapter.

**Table 59-3. EWM Signal Descriptions**

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active low.	I
EWM_OUT_b	EWM reset out signal	O
lpo_clk[3:0]	Low power clock sources for running counter	I

## 59.5 Memory Map/Register Definition

This section contains the module memory map and registers.

**NOTE**

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

### 59.5.1 EWM register descriptions

#### 59.5.1.1 EWM memory map

EWM base address: 400B\_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Register (CTRL)	8	RW	00h
1h	Service Register (SERV)	8	WORZ	00h
2h	Compare Low Register (CMPL)	8	RWONC E	00h
3h	Compare High Register (CMPH)	8	RWONC E	FFh
4h	Clock Control Register (CLKCTRL)	8	RWONC E	00h
5h	Clock Prescaler Register (CLKPRESCALER)	8	RWONC E	00h

## 59.5.1.2 Control Register (CTRL)

### 59.5.1.2.1 Offset

Register	Offset
CTRL	0h

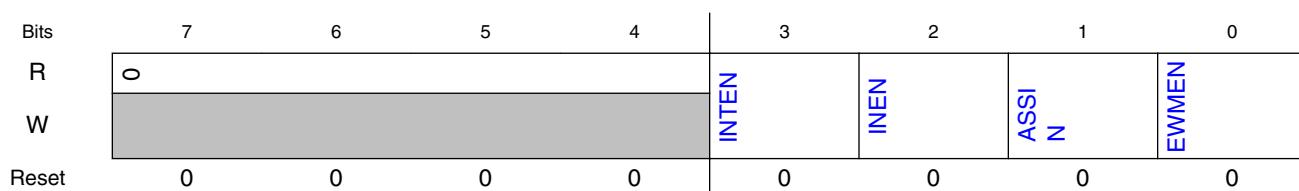

### 59.5.1.2.2 Function

The CTRL register is cleared by any reset.

#### NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

### 59.5.1.2.3 Diagram

### 59.5.1.2.4 Fields

Field	Function
7-4	Reserved
—	
3 INTEN	Interrupt Enable.  This bit when set and EWM_OUT_b is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0. 0b - Deasserts the interrupt request. 1b - Generates an interrupt request, when EWM_OUT_b is asserted.
2 INEN	Input Enable.  This bit when set, enables the EWM_in port. 0b - EWM_in port is disabled. 1b - EWM_in port is enabled.
1 ASSIN	EWM_in's Assertion State Select.  Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one. 0b - Default assert state of the EWM_in signal. 1b - Inverts the assert state of EWM_in signal.
0 EWMEN	EWM enable.  This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_OUT_b signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit. 0b - EWM module is disabled. 1b - EWM module is enabled.

### 59.5.1.3 Service Register (SERV)

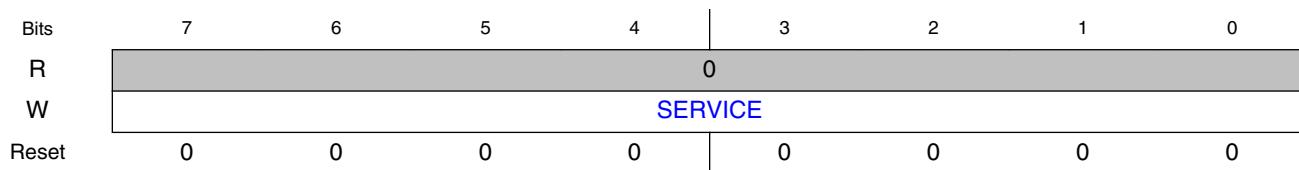

#### 59.5.1.3.1 Offset

Register	Offset
SERV	1h

#### 59.5.1.3.2 Function

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

### 59.5.1.3.3 Diagram

### 59.5.1.3.4 Fields

Field	Function
7-0 SERVICE	<p>The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true.</p> <ul style="list-style-type: none"> <li>• The first or second data byte is not written correctly.</li> <li>• The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <i>EWM_refresh_time</i>.</li> </ul> <p>63 peripheral bus clock cycles are required for <i>EWM_refresh_time</i></p>

## 59.5.1.4 Compare Low Register (CMPL)

### 59.5.1.4.1 Offset

Register	Offset
CMPL	2h

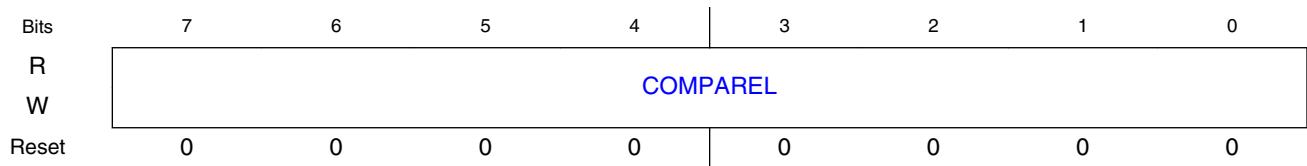

### 59.5.1.4.2 Function

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

#### NOTE

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

### 59.5.1.4.3 Diagram

### 59.5.1.4.4 Fields

Field	Function
7-0	COMPAREL
COMPAREL	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required.

## 59.5.1.5 Compare High Register (CMPH)

### 59.5.1.5.1 Offset

Register	Offset
CMPH	3h

### 59.5.1.5.2 Function

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

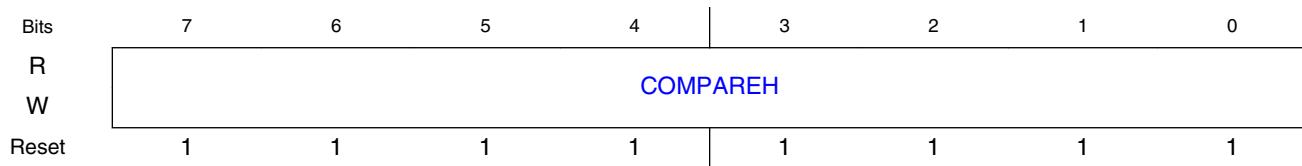

#### NOTE

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

#### NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

### 59.5.1.5.3 Diagram

### 59.5.1.5.4 Fields

Field	Function
7-0 COMPAREH	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required.

## 59.5.1.6 Clock Control Register (CLKCTRL)

### 59.5.1.6.1 Offset

Register	Offset
CLKCTRL	4h

### 59.5.1.6.2 Function

This CLKCTRL register is reset to 0x00 after a CPU reset.

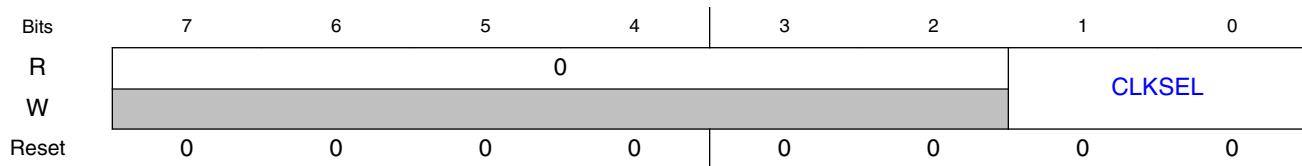

#### NOTE

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

#### NOTE

User should select the required low power clock before enabling the EWM.

### 59.5.1.6.3 Diagram

### 59.5.1.6.4 Fields

Field	Function
7-2 —	reserved
1-0 CLKSEL	<p>CLKSEL</p> <p>EWM has 4 possible low power clock sources for running EWM counter. One of the clock source can be selected by writing into this field.</p> <ul style="list-style-type: none"> <li>• 00 - lpo_clk[0] will be selected for running EWM counter.</li> <li>• 01 - lpo_clk[1] will be selected for running EWM counter.</li> <li>• 10 - lpo_clk[2] will be selected for running EWM counter.</li> <li>• 11 - lpo_clk[3] will be selected for running EWM counter.</li> </ul>

## 59.5.1.7 Clock Prescaler Register (CLKPRESCALER)

### 59.5.1.7.1 Offset

Register	Offset
CLKPRESCALER	5h

### 59.5.1.7.2 Function

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

#### NOTE

This register can be written only once after a CPU reset.

Writing this register more than once generates a bus transfer error.

#### NOTE

Write the required prescaler value before enabling the EWM.

**NOTE**

The implementation of this register is chip-specific. See the Chip Configuration details.

**59.5.1.7.3 Diagram****59.5.1.7.4 Fields**

Field	Function
7-0 CLK_DIV	Selected low power clock source for running the EWM counter can be prescaled as below. <ul style="list-style-type: none"> <li>Prescaled clock frequency = low power clock source frequency / ( 1 + CLK_DIV )</li> </ul>

# Chapter 60

## On Chip Cross Triggers Overview

### 60.1 Overview

This chip integrates an on-chip cross trigger network. The following diagram shows the cross trigger network of this device.

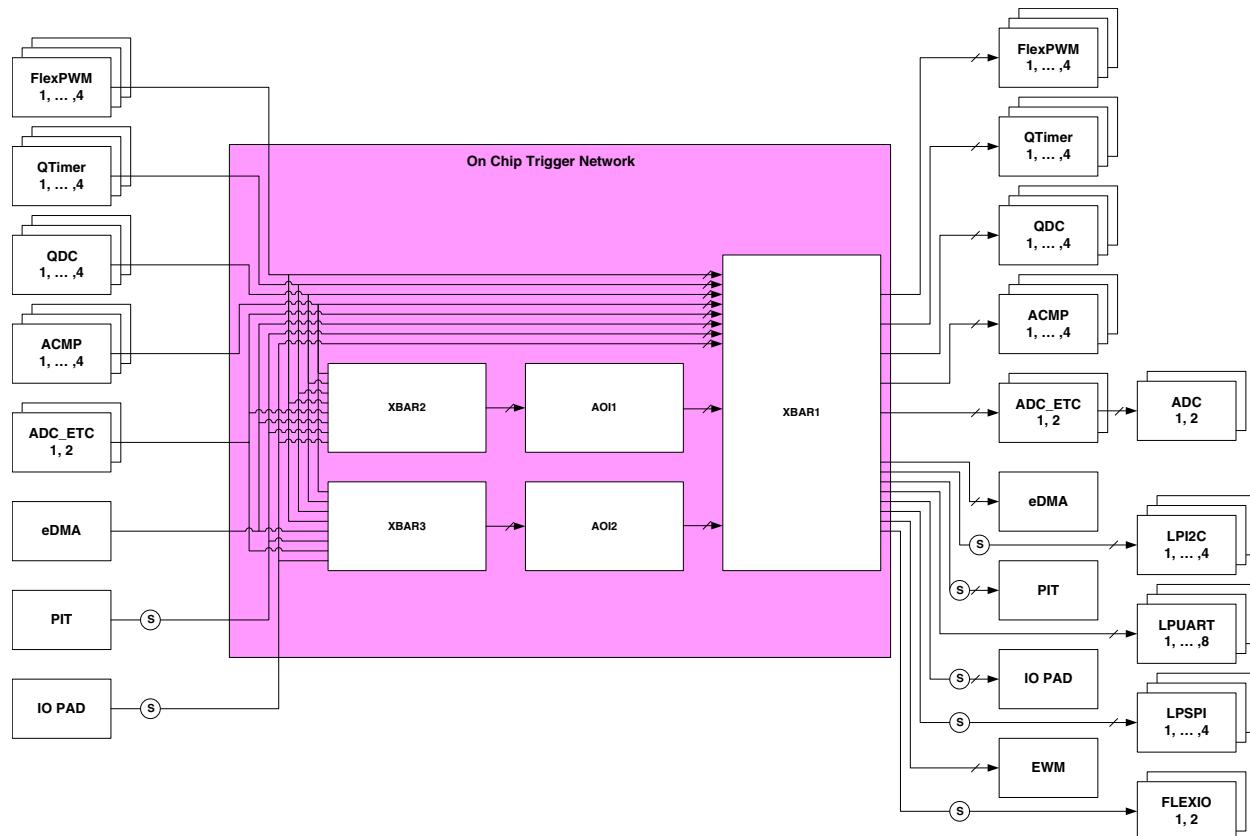

Figure 60-1. On-Chip Cross Trigger Network

## 60.1.1 Cross BAR (XBAR)

Each crossbar switch is an array of MUXes with shared inputs. Each mux output provides one output of the crossbar. The number of inputs and the number of MUXes/outputs is user configurable and registers are provided to select which of the shared inputs is routed to each output. The crossbar switches are used to reconfigure data paths between peripherals (peripheral output to peripheral input) as well as between peripherals and GPIO.

## 60.1.2 And-Or-Inverter (AOI)

The AOI module provides an universal Boolean function generator using a four term sum of products expression, with each product term containing true or complement values of the four selected inputs (A, B, C, D).

# Chapter 61

## Inter-Peripheral Crossbar Switch A (XBARA)

### 61.1 Chip-specific XBAR information

Table 61-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

On this device, for XBAR1 (see the XBARA chapter), the number of inputs is 88, and the number of outputs is 132. For XBAR2 and XBAR3 (see the XBARB chapter), the number of inputs is 64, and the number of outputs is 16.

#### NOTE

The XBAR\_INn and XBAR\_OUTn signals (n=4 to 19) share the same IOs. The user needs to configure the corresponding IOMUXC\_GPR\_GPR6[IOMUXC\_XBAR\_DIR\_SEL\_n] bit to use either XBAR\_IN or XBAR\_OUT.

### 61.2 Overview

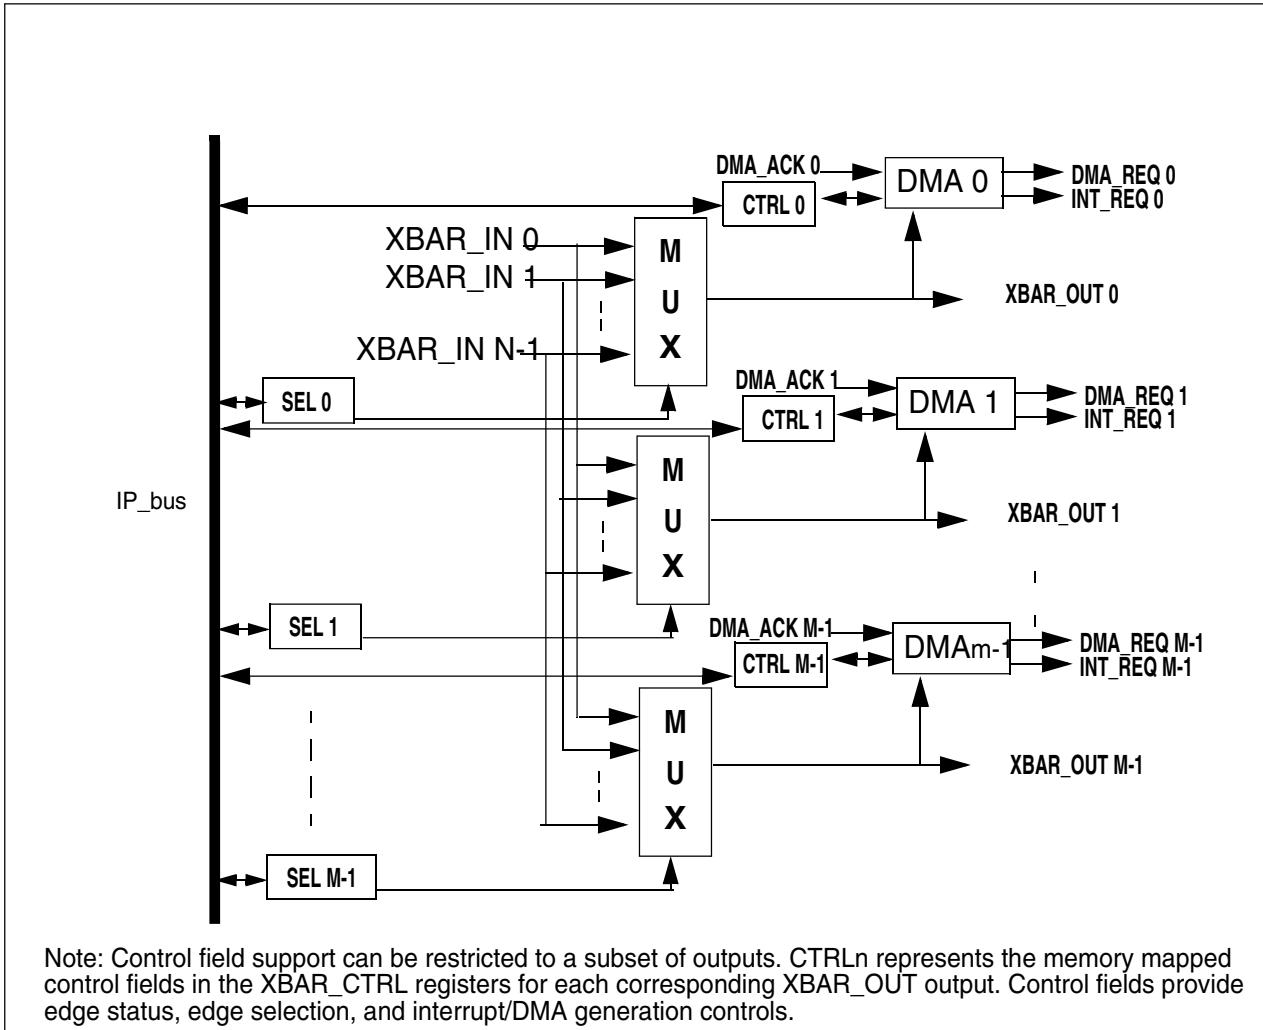

This module implements an array of M N-input combinational muxes. All muxes share the same N inputs in the same order, but each mux has its own independent select field.

The intended application of this module is to provide a flexible crossbar switch function that allows any input (typically from external GPIO or internal module outputs) to be connected to any output (typically to external GPIO or internal module inputs) under user control. This is used to allow user configuration of data paths between internal modules and between internal modules and GPIO.

A subset of the muxes can be configured to support edge detection and either interrupt or DMA request generation based on detected signal edges on the mux output. This allows signal transitions on the signals feeding the crossbar to trigger interrupts or initiate data transfers via DMA into or out of other system modules.

## 61.2.1 Block Diagram

The block diagram for XBAR is shown in [Figure 61-1](#).

**Figure 61-1. XBAR Block Diagram**

## 61.2.2 Features

The XBAR module design includes these distinctive features:

- M identical N-input muxes with individual select fields.
- Edge detection with associated interrupt or DMA request generation for a subset of mux outputs.
- Memory mapped registers with IPBus interface for select and control fields.
- Register write protection input signal.

## 61.2.3 Modes of Operation

The XBAR module design operates in only a single mode of operation: Functional Mode. The various operation modes are detailed in [Functional Mode](#).

## 61.3 Functional Description

### 61.3.1 General

The XBAR module has only one mode of operation, functional mode.

### 61.3.2 Functional Mode

The value of each mux output is  $\text{XBAR\_OUT}[n] = \text{XBAR\_IN}[\text{SEL}_n]$ . The  $\text{SEL}_n$  select values are configured in the XBAR\_SEL registers. All muxes share the same inputs in the same order.

The following is an example to show how to specify the specific input for the specific output:

To select XBAR\_IN03 to connect with XBAR\_OUT07, according to the index of XBAR\_OUT07, select the SEL07 (same number with the selected XBAR\_OUT index) fields in the MSBs of the Select Register 3 XBAR\_SEL3, and assign the index (0x03, Hexadecimal) of the selected XBAR\_IN in it.

```
XBAR_SEL3 &= 0x0011; /*Clear the SEL7 fields
XBAR_SEL3 |= 0x0300; /*Assign the 0x03 to the SEL7 fields
```

A subset of XBAR\_OUT[\*] outputs has dedicated control fields in a Crossbar Control (XBAR\_CTRL) register. Control fields provide the ability to perform edge detection on the corresponding XBAR\_OUT output. Edge detection in turn can optionally be used to trigger an interrupt or DMA request. The intention is that, by detecting specified edges on signals propagating through the Crossbar, interrupts or DMA requests can be triggered to perform data transfers to or from other system components.

Control fields include an edge status field (STS), a detected edge type field (EDGE), and interrupt and DMA enable fields (IEN and DEN). STS<sub>n</sub> is set to 1 when an edge consistent with EDGEN occurs on XBAR\_OUT[n]. STS<sub>n</sub> is cleared by writing 1 to it. Writing 0 as no effect. See [Interrupts and DMA Requests](#) for details on the use of STS<sub>n</sub> for DMA and interrupt request generation.

### 61.3.3 Clocks

All sequential functionality is controlled by the Bus Clock.

### 61.3.4 Resets

The XBAR module can be reset by only a hard reset, which forces all registers to their reset state.

### 61.3.5 Interrupts and DMA Requests

For each XBAR\_OUT[\*] output with XBAR\_CTRL register support, DMA or interrupt functionality can be enabled by setting the corresponding XBAR\_CTRL register bit DEN<sub>n</sub> or IEN<sub>n</sub> to 1. DEN<sub>n</sub> and IEN<sub>n</sub> should not be set to 1 at the same time for the same output XBAR\_OUT[n].

Setting DEN<sub>n</sub> to 1 enables DMA functionality for XBAR\_OUT[n]. When DMA functionality is enabled, the output DMA\_REQ[n] reflects the value of STS<sub>n</sub>. Thus the DMA request asserts when the edge specified by EDGEN is detected on XBAR\_OUT[n]. Also, a rising edge on DMA\_ACK[n] sets STS<sub>n</sub> to zero and thus clears the DMA request. When DEN is 0, DMA\_REQ[n] is held low and DMA\_ACK[n] is ignored.

Setting IEN<sub>n</sub> to 1 enables interrupt functionality for XBAR\_OUT[n]. When interrupt functionality is enabled, the output INT\_REQ[n] reflects the value of STS<sub>n</sub>. Thus the interrupt request asserts when the edge specified by EDGEN is detected on XBAR\_OUT[n]. The interrupt request is cleared by writing a 1 to STS<sub>n</sub>. When IEN<sub>n</sub> is 0, INT\_REQ[n] is held low.

## 61.4 External Signals

The following table summarizes the module's external signals.

**Table 61-2. Control Signal Properties**

Name	I/O Type	Function	Reset State	Notes
XBAR_OUT [0:NUMOUT-1]	O	Mux Outputs with configurable width	XBAR_IN[0]	
XBAR_IN [0:NUMIN-1]	I	Mux Inputs with configurable width	*	
DMA_REQ	O	DMA request	0	
INT_REQ	O	Interrupt request	0	
DMA_ACK	I	DMA acknowledge	0	

At reset, each output XBAR\_OUT[\*] contains the reset value of the signal driving XBAR\_IN[0].

### 61.4.1 XBAR\_OUT[0:NUM\_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR\_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR\_OUT[n] = XBAR\_IN[SELn].

### 61.4.2 XBAR\_IN[0:NUM\_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

### 61.4.3 DMA\_REQ[n] - DMA Request Output(s)

DMA\_REQ[n] is a DMA request to the DMA controller.

### 61.4.4 DMA\_ACK[n] - DMA Acknowledge Input(s)

DMA\_ACK[n] is a DMA acknowledge input from the DMA controller.

## 61.4.5 INT\_REQ[n] - Interrupt Request Output(s)

INT\_REQ[n] is an interrupt request output to the interrupt controller.

## 61.5 Memory Map and Register Descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR\_IN[\*]) is muxed to each mux output (XBAR\_OUT[\*]). There is one SELn field per mux and therefore one per XBAR\_OUT output. Crossbar output XBAR\_OUT[n] presents the value of XBAR\_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR\_IN and XBAR\_OUT are application specific and are described in the [Interrupts, DMA Events, and XBAR Assignments chapter](#) details.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR\_OUT[\*] outputs.

Field	Description
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 SEL131	Input (XBARA_INn) to be muxed to XBARA_OUT131 (refer to Functional Description section for input/output assignment)
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SEL130	Input (XBARA_INn) to be muxed to XBARA_OUT130 (refer to Functional Description section for input/output assignment)

## 61.5.67 Crossbar A Control Register 0 (XBARAx\_CTRL0)

Use this register to configure edge detection, interrupt, and DMA features for the XBAR\_OUT0 and XBAR\_OUT1 outputs.

The XBAR\_CTRL registers are organized similarly to the XBAR\_SEL registers, with control fields for two XBAR\_OUT outputs in each register. In control register 0, the LSBs contain the control fields for XBAR\_OUT0, and the MSBs contain the control fields for XBAR\_OUT1.

Address: 403B\_C000h base + 84h offset = 403B\_C084h

Bit	15	14	13	12	11	10	9	8
Read		0		STS1	EDGE1	IEN1	DEN1	
Write				w1c				
Reset	0	0	0	0				0
Bit	7	6	5	4	3	2	1	0
Read		0		STS0	EDGE0	IENO	DENO	
Write				w1c				
Reset	0	0	0	0				0

**XBARAx\_CTRL0 field descriptions**

Field	Description
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 STS1	Edge detection status for XBAR_OUT1  This bit reflects the results of edge detection for XBAR_OUT1.  This field is set to 1 when an edge consistent with the current setting of EDGE1 is detected on XBAR_OUT1. This field is cleared by writing 1 to it or by a DMA_ACK1 reception when DEN1 is set. Writing 0 to the field has no effect.  When interrupt or DMA functionality is enabled for XBAR_OUT1, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared.  0 Active edge not yet detected on XBAR_OUT1 1 Active edge detected on XBAR_OUT1
11–10 EDGE1	Active edge for edge detection on XBAR_OUT1  This field selects which edges on XBAR_OUT1 cause STS1 to assert.  00 STS1 never asserts 01 STS1 asserts on rising edges of XBAR_OUT1 10 STS1 asserts on falling edges of XBAR_OUT1 11 STS1 asserts on rising and falling edges of XBAR_OUT1
9 IEN1	Interrupt Enable for XBAR_OUT1  This bit enables the interrupt function on the corresponding XBAR_OUT1 output. When the interrupt is enabled, the output INT_REQ1 reflects the value STS1. When the interrupt is disabled, INT_REQ1 remains low. The interrupt request is cleared by writing a 1 to STS1.  <b>Restriction:</b> IEN1 and DEN1 should not both be set to 1.  0 Interrupt disabled 1 Interrupt enabled
8 DEN1	DMA Enable for XBAR_OUT1  This bit enables the DMA function on the corresponding XBAR_OUT1 output. When enabled, DMA_REQ1 presents the value STS1. When disabled, the DMA_REQ1 output remains low.  <b>Restriction:</b> IEN1 and DEN1 should not both be set to 1.  0 DMA disabled 1 DMA enabled
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 STS0	Edge detection status for XBAR_OUT0  This bit reflects the results of edge detection for XBAR_OUT0.  This field is set to 1 when an edge consistent with the current setting of EDGE0 is detected on XBAR_OUT0. This field is cleared by writing 1 to it or by a DMA_ACK0 reception when DEN0 is set. Writing 0 to the field has no effect.  When interrupt or DMA functionality is enabled for XBAR_OUT0, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared.

*Table continues on the next page...*

**XBARAx\_CTRL0 field descriptions (continued)**

Field	Description
	0 Active edge not yet detected on XBAR_OUT0 1 Active edge detected on XBAR_OUT0
3–2 EDGE0	Active edge for edge detection on XBAR_OUT0  This field selects which edges on XBAR_OUT0 cause STS0 to assert.  00 STS0 never asserts 01 STS0 asserts on rising edges of XBAR_OUT0 10 STS0 asserts on falling edges of XBAR_OUT0 11 STS0 asserts on rising and falling edges of XBAR_OUT0
1 IEN0	Interrupt Enable for XBAR_OUT0  This bit enables the interrupt function on the corresponding XBAR_OUT0 output. When the interrupt is enabled, the output INT_REQ0 reflects the value STS0. When the interrupt is disabled, INT_REQ0 remains low. The interrupt request is cleared by writing a 1 to STS0.  <b>Restriction:</b> IEN0 and DEN0 should not both be set to 1.  0 Interrupt disabled 1 Interrupt enabled
0 DEN0	DMA Enable for XBAR_OUT0  This bit enables the DMA function on the corresponding XBAR_OUT0 output. When enabled, DMA_REQ0 presents the value STS0. When disabled, the DMA_REQ0 output remains low.  <b>Restriction:</b> IEN0 and DEN0 should not both be set to 1.  0 DMA disabled 1 DMA enabled

**61.5.68 Crossbar A Control Register 1 (XBARAx\_CTRL1)**

Use this register to configure edge detection, interrupt, and DMA features for the XBAR\_OUT2 and XBAR\_OUT3 outputs.

The XBAR\_CTRL registers are organized similarly to the XBAR\_SEL registers, with control fields for two XBAR\_OUT outputs in each register. In control register 1, the LSBs contain the control fields for XBAR\_OUT2, and the MSBs contain the control fields for XBAR\_OUT3.

Address: 403B\_C000h base + 86h offset = 403B\_C086h

Bit	15	14	13	12	11	10	9	8
Read		0		STS3				
Write				w1c	EDGE3	IEN3	DEN3	
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read		0		STS2				
Write				w1c	EDGE2		IEN2	DEN2
Reset	0	0	0	0	0	0	0	0

**XBARAx\_CTRL1 field descriptions**

Field	Description
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 STS3	Edge detection status for XBAR_OUT3  This bit reflects the results of edge detection for XBAR_OUT3.  This field is set to 1 when an edge consistent with the current setting of EDGE3 is detected on XBAR_OUT3. This field is cleared by writing 1 to it or by a DMA_ACK3 reception when DEN3 is set. Writing 0 to the field has no effect.  When interrupt or DMA functionality is enabled for XBAR_OUT3, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared.  0 Active edge not yet detected on XBAR_OUT3 1 Active edge detected on XBAR_OUT3
11–10 EDGE3	Active edge for edge detection on XBAR_OUT3  This field selects which edges on XBAR_OUT3 cause STS3 to assert.  00 STS3 never asserts 01 STS3 asserts on rising edges of XBAR_OUT3 10 STS3 asserts on falling edges of XBAR_OUT3 11 STS3 asserts on rising and falling edges of XBAR_OUT3
9 IEN3	Interrupt Enable for XBAR_OUT3  This bit enables the interrupt function on the corresponding XBAR_OUT3 output. When the interrupt is enabled, the output INT_REQ3 reflects the value STS3. When the interrupt is disabled, INT_REQ3 remains low. The interrupt request is cleared by writing a 1 to STS3.  <b>Restriction:</b> IEN3 and DEN3 should not both be set to 1.  0 Interrupt disabled 1 Interrupt enabled
8 DEN3	DMA Enable for XBAR_OUT3  This bit enables the DMA function on the corresponding XBAR_OUT3 output. When enabled, DMA_REQ3 presents the value STS3. When disabled, the DMA_REQ3 output remains low.  <b>Restriction:</b> IEN3 and DEN3 should not both be set to 1.  0 DMA disabled 1 DMA enabled
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 STS2	Edge detection status for XBAR_OUT2  This bit reflects the results of edge detection for XBAR_OUT2.

*Table continues on the next page...*

**XBARAx\_CTRL1 field descriptions (continued)**

Field	Description
	<p>This field is set to 1 when an edge consistent with the current setting of EDGE2 is detected on XBAR_OUT2. This field is cleared by writing 1 to it or by a DMA_ACK2 reception when DEN2 is set. # Chapter 62

## Inter-Peripheral Crossbar Switch B (XBARB)

### 62.1 Chip-specific XBAR information

Table 62-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

On this device, for XBART (see the XBARA chapter), the number of inputs is 88, and the number of outputs is 132. For XBART2 and XBART3 (see the XBARB chapter), the number of inputs is 64, and the number of outputs is 16.

#### NOTE

The XBART\_INn and XBART\_OUTn signals (n=4 to 19) share the same IOs. The user needs to configure the corresponding IOMUXC\_GPR\_GPR6[IOMUXC\_XBAR\_DIR\_SEL\_n] bit to use either XBART\_IN or XBART\_OUT.

### 62.2 Overview

For a description of the general features and functionality of this module, refer to the [XBARA description](#).

## 62.3 Functional Description

For a functional description of this module, refer to the [XBARA functional description](#).

## 62.4 External Signals

The following table summarizes the module's external signals.

**Table 62-2. Control Signal Properties**

Name	I/O Type	Function	Reset State	Notes
XBAR_OUT [0:NUMOUT-1]	O	Mux Outputs with configurable width	XBAR_IN[0]	
XBAR_IN [0:NUMIN-1]	I	Mux Inputs with configurable width	*	

At reset, each output XBAR\_OUT[\*] contains the reset value of the signal driving XBAR\_IN[0].

### 62.4.1 XBAR\_OUT[0:NUM\_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR\_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR\_OUT[n] = XBAR\_IN[SELn].

### 62.4.2 XBAR\_IN[0:NUM\_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

## 62.5 Memory Map and Register Descriptions

This section provides information about the XBARB instance of the inter-peripheral crossbar switch.

This XBAR module has only select registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBABB\_IN[\*]) is muxed to each mux output (XBABB\_OUT[\*]). There is one SELn field per mux and therefore one per XBABB\_OUT output. Crossbar output XBABB\_OUT[n] presents the value of XBABB\_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBABB\_IN and XBABB\_OUT are application specific and are described in the [Interrupts, DMA Events, and XBABB Assignments chapter](#) details.

Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
XBAR resource assignments	XBAR	<a href="#">XBAR Resource Assignments</a>

### 63.2 Overview

The AND/OR/INVERT module (known simply as the AOI module) supports the generation of a configurable number of EVENT signals. Each output EVENTn is a configurable and/or/invert function of four associated AOI inputs: An, Bn, Cn, and Dn.

This module is designed to be integrated in conjunction with one or more inter-peripheral crossbar switch (XBAR) modules. A crossbar switch is typically used to select the 4\*n AOI inputs from among available peripheral outputs and GPIO signals. The n EVENTn outputs from the AOI module are typically used as additional inputs to a second crossbar switch, adding to it the ability to connect to its outputs an arbitrary 4-input boolean function of its other inputs.

The AOI controller is a slave peripheral module connecting event input indicators from a variety of device modules and generating event output signals that can be routed to an inter-peripheral crossbar switch or other peripherals. Its programming model is accessed through the standard IPS (Sky Blue) slave interface. The module is designed to be very configurable in terms of the functionality of its integrated AOI functions.

### 63.2.1 Block diagram

The AOI module supports a configurable number of event outputs, where each event output represents a user-programmed combinational boolean function based on four event inputs. The key features of this module include:

- Four dedicated inputs for each event output
- User-programmable combinational boolean function evaluation for each event output
- Memory-mapped device connected to a slave peripheral (IPS) bus
- Configurable number of event outputs

#### **NOTE**

The connections from the AOI module outputs to other functions is SoC-specific.

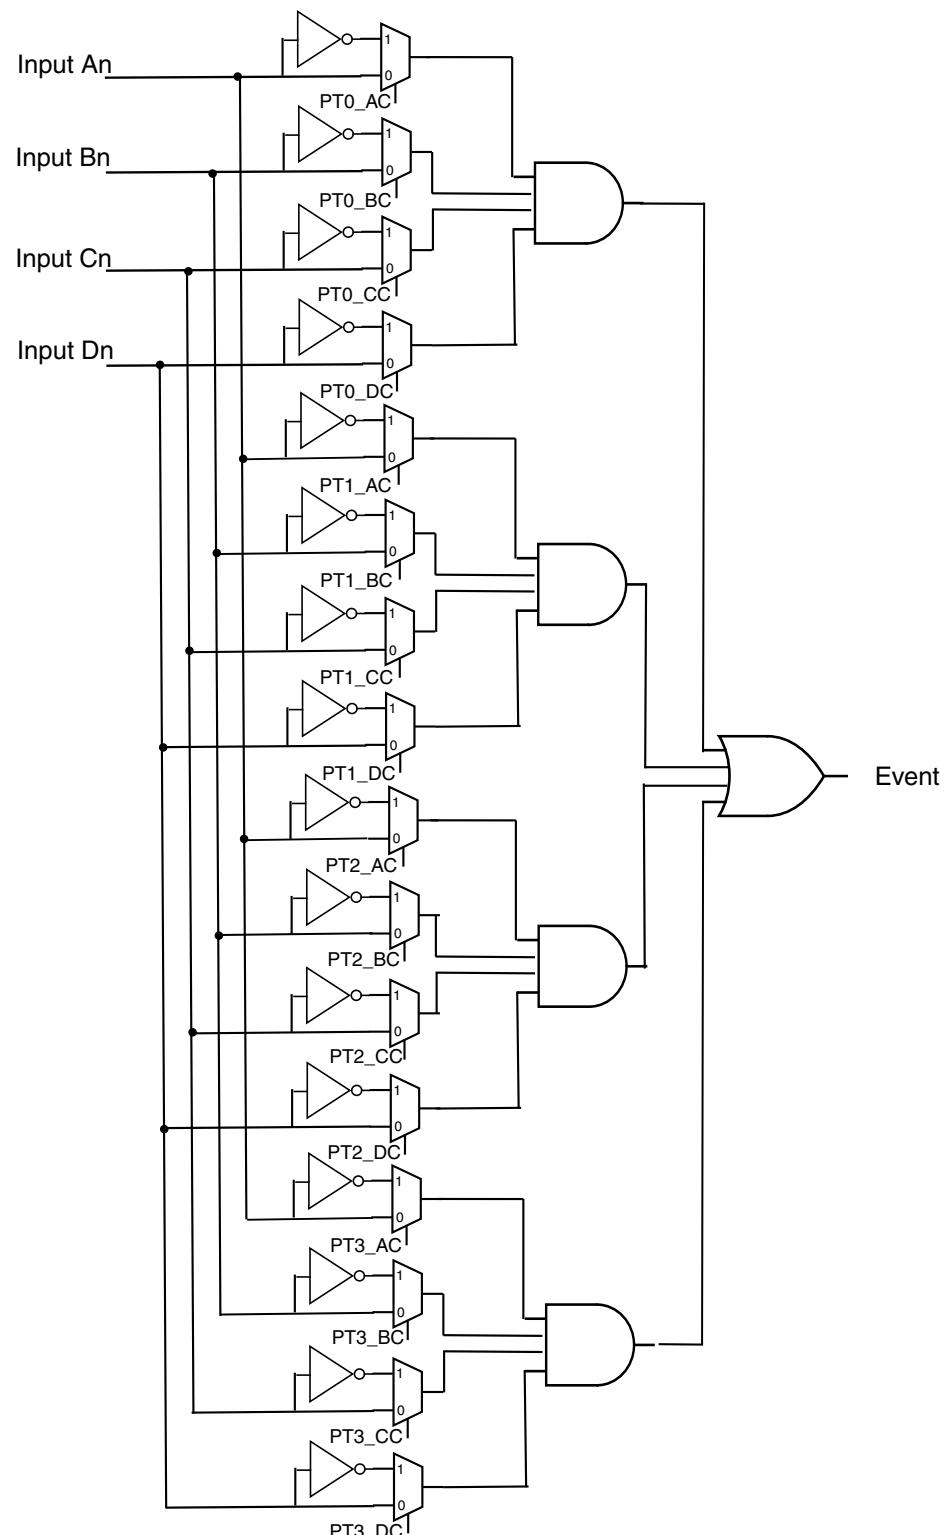

Figure 63-1. Simplified AOI Block Diagram

## 63.2.2 Features

The major features of the AOI module are summarized below:

- Highly programmable module for creating combinational boolean events for use as hardware triggers
  - Each channel has four event inputs and one output
  - Evaluates a combinational boolean expression as the sum of four products where each product term includes all four selected input sources available as true or complement values
  - Event output is formed as purely combinational logic and operates as a hardware trigger
- Memory-mapped device connected to the slave peripheral (IPS) bus
  - Programming model organized per channel for simplified software

## 63.2.3 Modes of Operation

The AOI module does not support any special modes of operation. As shown in [Figure 63-1](#), its operation is primarily controlled by the selected event inputs and outputs. Additionally, as a memory-mapped device located on the slave peripheral bus, it responds based strictly on memory address for accesses to its programming model.

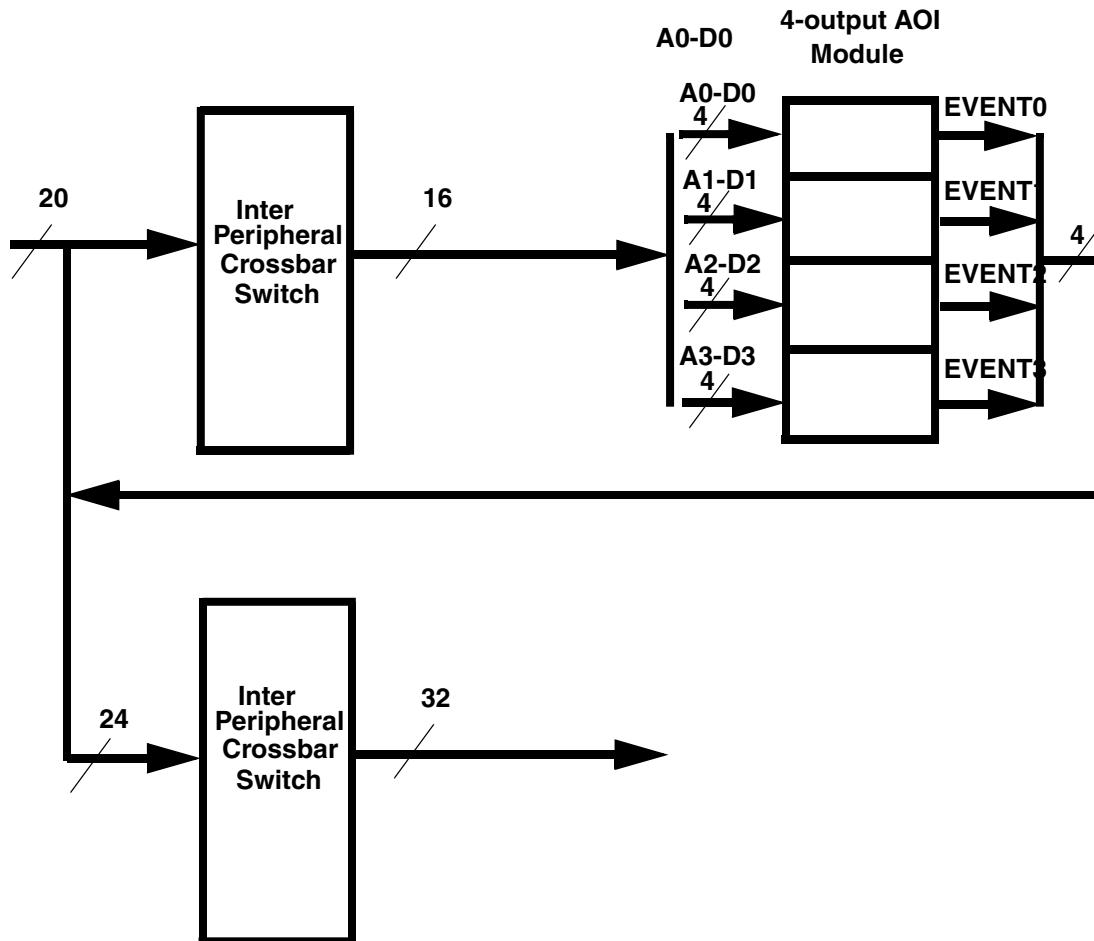

The AOI module resides in the slave peripheral *bus clock domain*.

## 63.3 Functional Description

The AOI is a highly programmable module for creating combinational boolean outputs for use as hardware triggers. Each AOI output channel, as shown in [Figure 63-1](#), has one logic function:

- Evaluation of a combinational boolean expression as a sum of four products where each product term includes all four selected input sources available as true or complement values

A typical application of the AOI module is to be integrated with one or more inter-peripheral crossbar switch modules as illustrated in the following figure. The 20 external inputs are shared by two crossbar switch modules. The crossbar switch on the top is used to select the inputs to four 4-input AOI functions in the AOI module. The outputs of these four AOI functions are output from the AOI module and are added to the original 20 external inputs to provide a total of 24 inputs to the bottom crossbar switch. As a result, the bottom crossbar can not only direct any of the original 20 external inputs to any of its outputs, it can also now direct any one of four 4-input AOI functions of those external inputs to any of its outputs.

**Figure 63-2. Integration Example of AOI with two Inter-Peripheral Crossbar Switches**

### 63.3.1 Configuration Examples for the Boolean Function Evaluation

This section presents examples of the programming model configuration for simple boolean expressions.

The AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). Specifically, the event output is defined by the following “4 x 4” boolean expression:

```
EVENTn
= (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 0
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 1
```

## Functional Description

```
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 2
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 3
```

where each selected input term in each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses eight bits of configuration information, two bits for each of the four selected event inputs. The actual boolean expression implemented in each channel is:

```
EVENTn
= (PT0_AC[0] & An | PT0_AC[1] & ~An) // product term 0
& (PT0_BC[0] & Bn | PT0_BC[1] & ~Bn)
& (PT0_CC[0] & Cn | PT0_CC[1] & ~Cn)
& (PT0_DC[0] & Dn | PT0_DC[1] & ~Dn)

| (PT1_AC[0] & An | PT1_AC[1] & ~An) // product term 1
& (PT1_BC[0] & Bn | PT1_BC[1] & ~Bn)
& (PT1_CC[0] & Cn | PT1_CC[1] & ~Cn)
& (PT1_DC[0] & Dn | PT1_DC[1] & ~Dn)

| (PT2_AC[0] & An | PT2_AC[1] & ~An) // product term 2
& (PT2_BC[0] & Bn | PT2_BC[1] & ~Bn)
& (PT2_CC[0] & Cn | PT2_CC[1] & ~Cn)
& (PT2_DC[0] & Dn | PT2_DC[1] & ~Dn)

| (PT3_AC[0] & An | PT3_AC[1] & ~An) // product term 3
& (PT3_BC[0] & Bn | PT3_BC[1] & ~Bn)
& (PT3_CC[0] & Cn | PT3_CC[1] & ~Cn)
& (PT3_DC[0] & Dn | PT3_DC[1] & ~Dn)
```

where the bits of the combined {BFCRT01n,BFCRT23n} registers correspond to the  $\text{PT}\{0\text{-}3\}_{\{A,B,C,D\}C[1:0]}$  terms in the equation.

Consider the settings of the combined 32-bit {BFCRT01n,BFCRT23n} registers for several simple boolean expressions as shown in [Table 63-2](#).

**Table 63-2. BFCRTn Values for Simple Boolean Expressions**

Event Output Expression	PT0	PT1	PT2	PT3	{BFCRT01, BFCRT23}
A & B	A & B	0	0	0	01011111_00000000_00000000_00000000
A & B & C	A & B & C	0	0	0	01010111_00000000_00000000_00000000
(A & B & C) + D	A & B & C	D	0	0	01010111_11111101_00000000_00000000
A + B + C + D	A	B	C	D	01111111_11011111_11110111_11111101
(A & ~B) + (~A & B)	A & ~B	~A & B	0	0	01101111_10011111_00000000_00000000

As can be seen in these examples, the resulting logic provides a simple yet powerful boolean function evaluation for defining an event output.

### 63.3.2 AOI Timing Between Inputs and Outputs

Each EVENTn output of the AOI module is a combination function of its four dedicated inputs An, Bn, Cn, and Dn. Propagation through the AOI and any associated inter-peripheral crossbar switch modules is intended to be single bus clock cycle.

### 63.3.3 Clocks

The bus clock is used for register accesses by the system, but AOI functions themselves are asynchronous and do not use a clock.

## 63.4 External Signal Description

The AOI module does not directly support any external interfaces. There may be package input signals (indirectly) connected to the module as event inputs, but since the *AOI does not include any input synchronization hardware*, this function must be handled before the event input signals are routed into the module.

## 63.5 Memory Map and Register Descriptions

The AOI module supports access to its programming model via a 16-bit peripheral bus connection. The module is designed to support 16-bit accesses only. Functionality for accesses of other widths is undefined.

### 63.5.1 AOI register descriptions

The AOI module supports a specific number of event outputs. Each output EVENTn outputs a four-term AOI function of four binary inputs: An, Bn, Cn, and Dn. A pair of 16-bit registers configures this four-term AOI function: The two registers BFCRT01n and BFCRT23n define the configuration for the evaluation of the Boolean function defining EVENTn, where n is the event output channel number. The BFCRT01n register defines the configuration of product terms 0 and 1, and the BFCRT23n register defines the configuration of product terms 2 and 3.

## Memory Map and Register Descriptions

The AOI module provides a universal Boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (An, Bn, Cn, Dn). Specifically, the EVENTn output is defined by the following "4 x 4" Boolean expression:

```
EVENTn
= (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 0
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 1
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 2
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 3
```

where each selected input of each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. The resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

These AOI functions are combinational in nature and are intended to be sampled and used synchronously.

### 63.5.1.1 AOI memory map

# Chapter 64

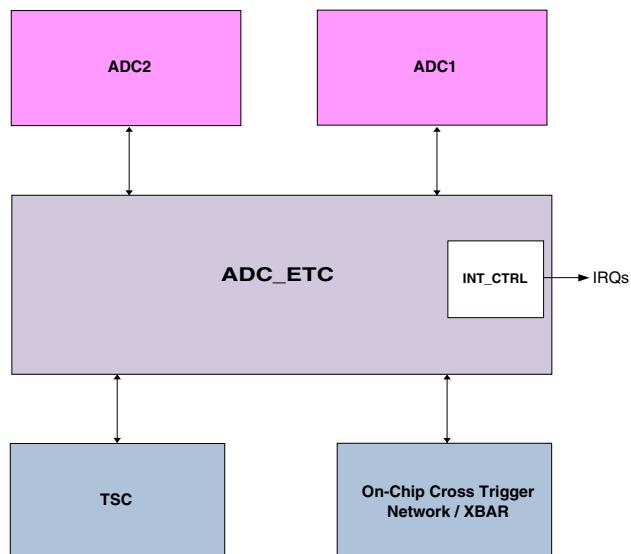

## Analog Overview

### 64.1 Overview

The following analog modules are integrated in this chip:

- Analog-Digital-Converter (ADC) - Supports up to 1MS/s sampling rate and up to 16 single-ended external analog inputs
- Touch Screen Controller (TSC) - Responsible for providing control of the ADC and the touch screen analog block to form a touch screen system
- ADC External Trigger Control (ADC\_ETC) - Enables multiple users to share a ADC module in a Time-Division-Multiplexing (TDM) method
- Comparator (CMP) - Operational over the entire supply range and features a integrated 6-bit DAC and a integrated 8 to 1 channel mux

Below is the simplified block diagram:

**Figure 64-1. Block Diagram (Simplified)**

### 64.1.1 Analog-to-Digital Converter (ADC)

The ADC module features a linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy.

It has three possible states:

- Disabled State - The ADC module is disabled
- Idle state - The ADC module is idle, waiting on a conversion to be initiated
- Conversion State - In this mode, the ADC module can perform analog-to-digital conversion on any of the software selectable channels, using the successive approximation algorithm

### 64.1.2 Touch Screen Control (TSC)

The TSC helps achieve the function of touch detection and touch location detection. The controller utilizes the ADC hardware trigger function and control switches in the touch screen analog block to form a touch screen system . The controller only supports 4-wire or 5-wire screen touch modes.

### 64.1.3 ADC External Trigger Control (ADC\_ETC)

The ADC\_ETC module enables multiple users to share a ADC module. It manages the external trigger mode (HWT) of the ADCs and supports up to x8 HWT for each ADC. It is capable of triggering dual ADCs in SyncMode (controlled by the same trigger source) or AsyncMode (controlled by separate trigger source). Every ADC HWT can be configured with a Back-to-Back (B2B) and Interrupt Enable (IE) settings and each external trigger can be configured with a fixed priority.

### 64.1.4 Comparator (CMP)

The analog comparator (CMP) allows for comparing two analog input voltages while the Analog MUX allows for selecting an analog input signal from eight channels. The CMP is operational across the full range of the supply voltage. The integrated 6-bit DAC provides a selectable voltage reference for applications where voltage reference is needed.

The CMPS share the same 3.3V reference voltage with the ADCs.

# Chapter 65

#### NOTE

$V_{in1}$  and  $V_{in2}$  are all connected to  $V_{DDA}$ , on this device.

### 65.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference  $V_{in}$  into 64 voltage levels. A 6-bit digital signal

input selects the output voltage level, which varies from  $V_{in}$  to  $V_{in}/64$ .  $V_{in}$  can be selected from two voltage sources,  $V_{in1}$  and  $V_{in2}$ . The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

## 65.2.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer
- Functional in all modes of operation
- The window and filter functions are not available in the following modes:
  - Stop
  - VLPS

## 65.2.2 6-bit DAC key features

The 6-bit DAC has the following features:

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

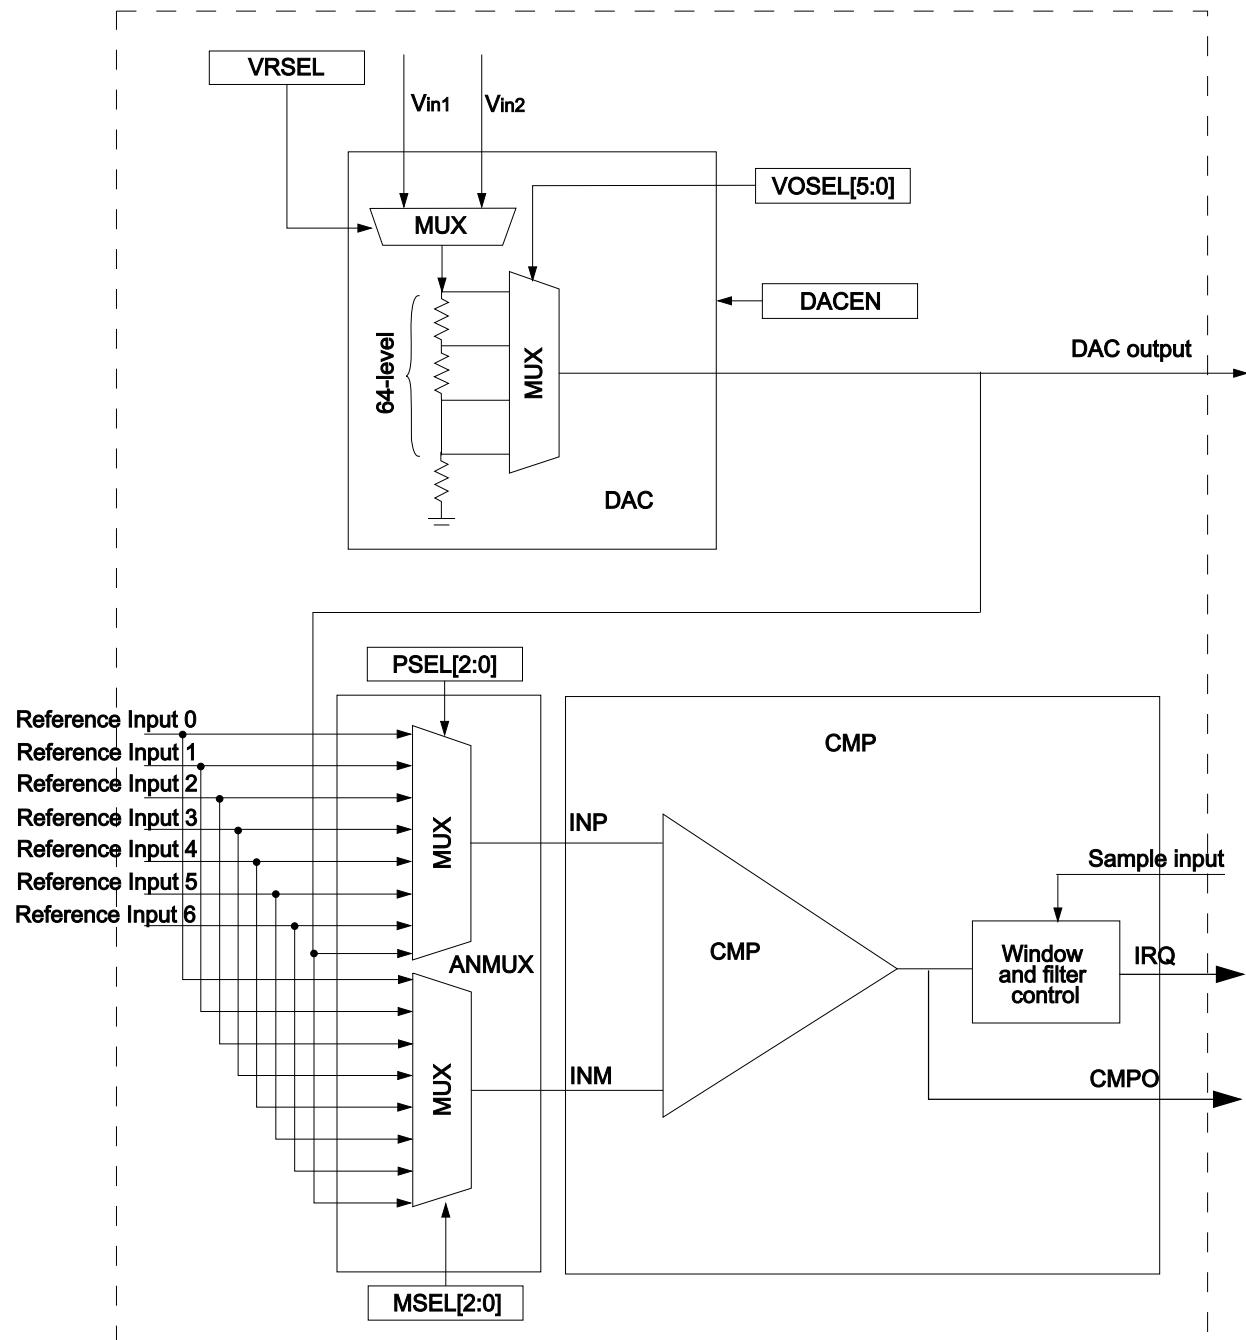

## 65.2.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel mux
- Operational over the entire supply range

## 65.2.4 CMP, DAC and ANMUX diagram

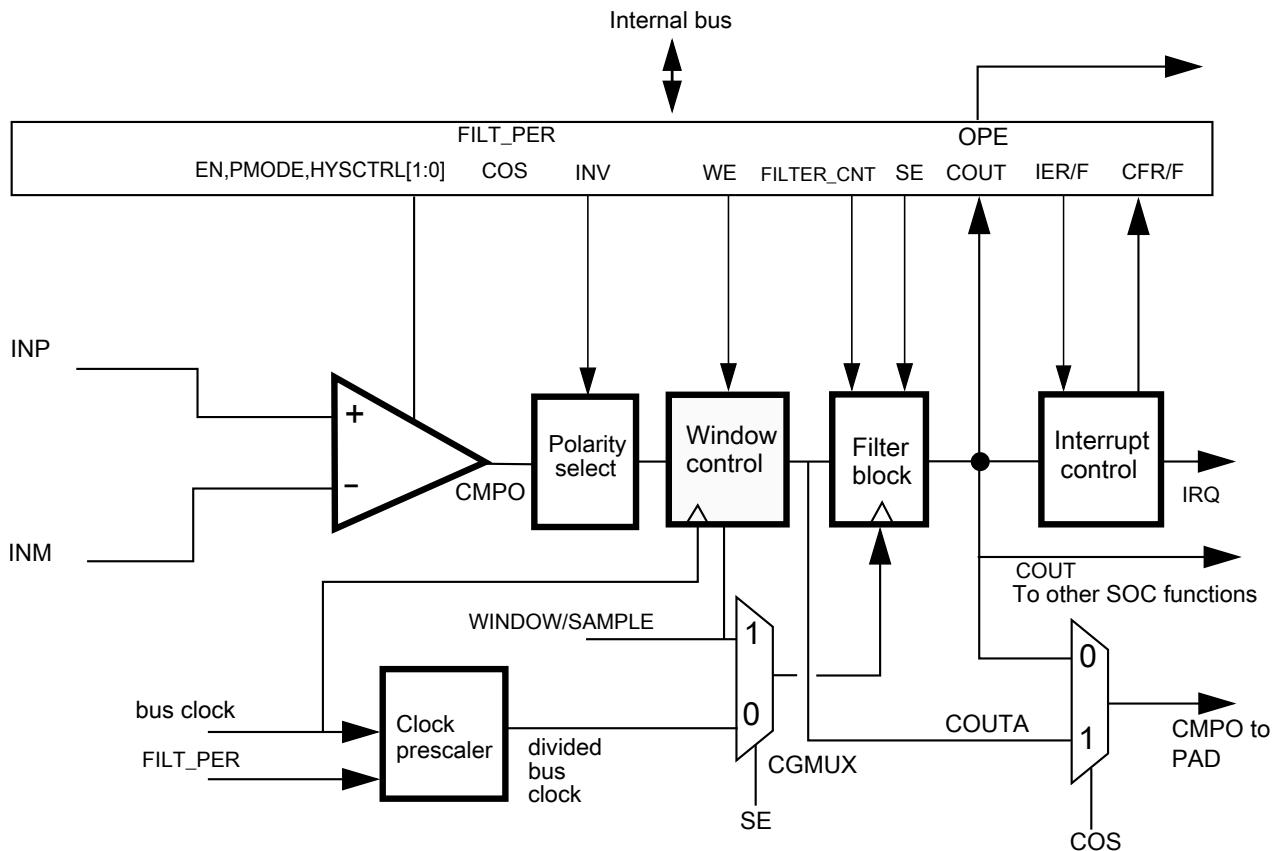

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

**Figure 65-1. CMP, DAC and ANMUX block diagram**

## 65.2.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

**Figure 65-2. Comparator module block diagram**

In the CMP block diagram:

- The Window Control block is bypassed when CR1[WE] = 0
- If CR1[WE] = 1, the comparator output will be sampled on every bus clock when WINDOW=1 to generate COUTA. Sampling does NOT occur when WINDOW = 0.
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and CR0[FILTER\_CNT] is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and CR0[FILTER\_CNT] is set greater than 0x01.
  - If CR1[SE] = 1, the external SAMPLE input is used as sampling clock
  - If CR1[SE] = 0, the divided bus clock is used as sampling clock

## Memory map/register definitions

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.
- CR1[WE] and CR1[SE] are mutually exclusive.

### 65.3.1 CMP Control Register 0 (CMPx\_CR0)

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	0		FILTER_CNT		0	0		
Write							HYSTCTR	
Reset	0	0	0	0	0	0	0	0

#### CMPx\_CR0 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 FILTER_CNT	Filter Sample Count  Represents the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state. For information regarding filter programming and latency, see the <a href="#">Functional description</a> .  000 Filter is disabled. If SE = 1, then COUT is a logic 0. This is not a legal state, and is not recommended. If SE = 0, COUT = COUTA. 001 One sample must agree. The comparator output is simply sampled. 010 2 consecutive samples must agree. 011 3 consecutive samples must agree. 100 4 consecutive samples must agree. 101 5 consecutive samples must agree. 110 6 consecutive samples must agree. 111 7 consecutive samples must agree.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
HYSTCTR	Comparator hard block hysteresis control  Defines the programmable hysteresis level. The hysteresis values associated with each level are device-specific. See the Data Sheet of the device for the exact values.  00 Level 0 01 Level 1 10 Level 2 11 Level 3

## 65.3.2 CMP Control Register 1 (CMPx\_CR1)

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read	SE	WE	0	PMODE	INV	COS	OPE	EN
Write	0	0	0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0

### CMPx\_CR1 field descriptions

Field	Description
7 SE	Sample Enable  At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations.  0 Sampling mode is not selected. 1 Sampling mode is selected.
6 WE	Windowing Enable  At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations.  0 Windowing mode is not selected. 1 Windowing mode is selected.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PMODE	Power Mode Select  See the electrical specifications table in the device Data Sheet for details.  0 Low-Speed (LS) Comparison mode selected. In this mode, CMP has slower output propagation delay and lower current consumption. 1 High-Speed (HS) Comparison mode selected. In this mode, CMP has faster output propagation delay and higher current consumption.
3 INV	Comparator INVERT  Allows selection of the polarity of the analog comparator function. It is also driven to the COUT output, on both the device pin and as SCR[COUT], when OPE=0.  0 Does not invert the comparator output. 1 Inverts the comparator output.
2 COS	Comparator Output Select  0 Set the filtered comparator output (CMPO) to equal COUT. 1 Set the unfiltered comparator output (CMPO) to equal COUTA.
1 OPE	Comparator Output Pin Enable

## 65.4 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM.

CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].

## 65.4.1 CMP functional modes

There are the following main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER\_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

**Table 65-2. Comparator sample/filter controls**

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation
1	0	X	X	X	X	<b>Disabled</b> See the <a href="#">Disabled mode (# 1).</a>
2A	1	0	0	0x00	X	<b>Continuous Mode</b> See the <a href="#">Continuous mode (#s 2A &amp; 2B).</a>
2B	1	0	0	X	0x00	
3A	1	0	1	0x01	X	<b>Sampled, Non-Filtered mode</b> See the <a href="#">Sampled, Non-Filtered mode (#s 3A &amp; 3B).</a>
3B	1	0	0	0x01	> 0x00	
4A	1	0	1	> 0x01	X	<b>Sampled, Filtered mode</b> See the <a href="#">Sampled, Filtered mode (#s 4A &amp; 4B).</a>
4B	1	0	0	> 0x01	> 0x00	
5A	1	1	0	0x00	X	<b>Windowed mode</b> Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the <a href="#">Windowed mode (#s 5A &amp; 5B).</a>
5B	1	1	0	X	0x00	
6	1	1	0	0x01	0x01–0xFF	<b>Windowed/Resampled mode</b>

*Table continues on the next page...*

**Table 65-2. Comparator sample/filter controls (continued)**

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation
						Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by FILT_PER to generate COUT. See the <a href="#">Windowed/Resampled mode (# 6).</a>
7	1	1	0	> 0x01	0x01–0xFF	<b>Windowed/Filtered mode</b> Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the <a href="#">Windowed/Filtered mode (#7).</a>

All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER\_CNT], and FPR[FILT\_PER] are illegal.

For cases where a comparator is used to drive a fault input, for example, inverter-control module such as PWM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

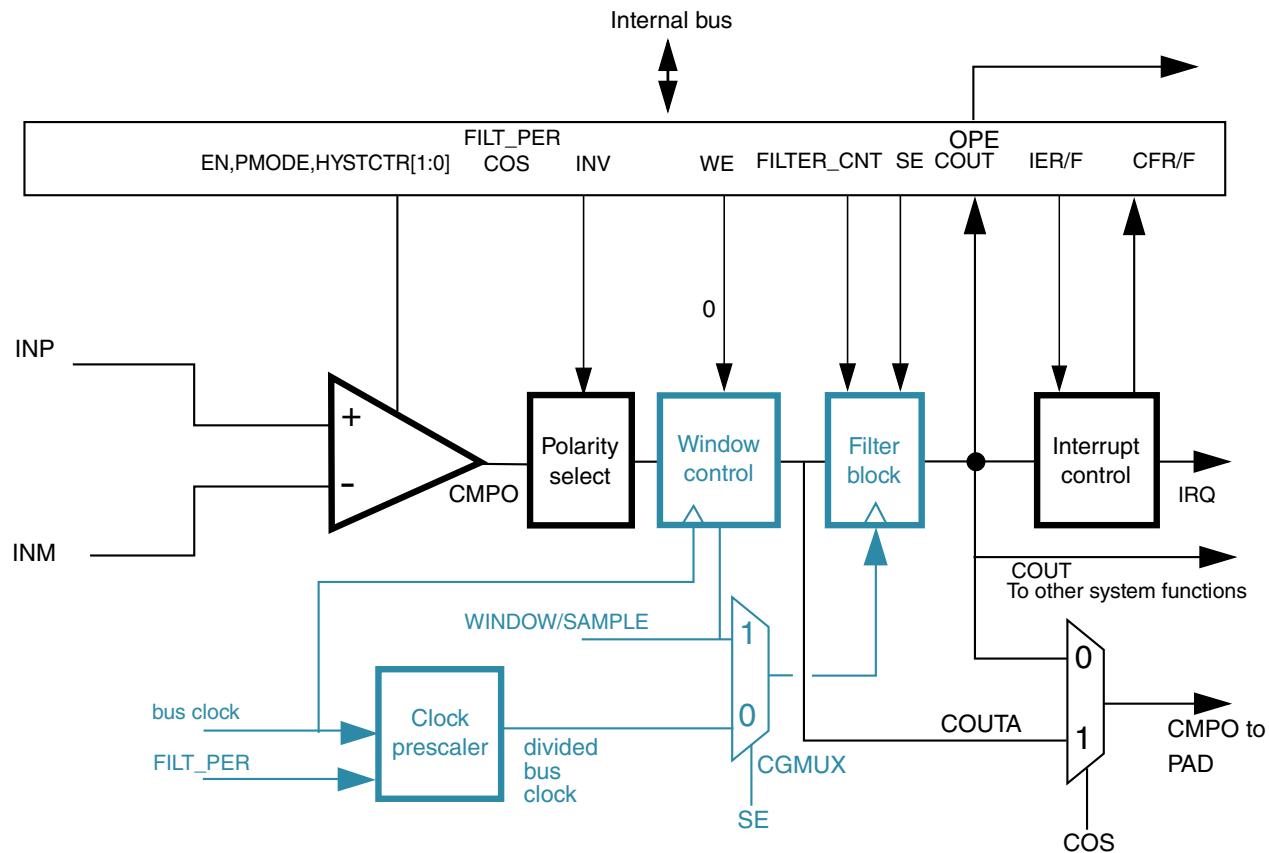

### Note

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER\_CNT]=0x00. This resets the filter to a known state.

#### 65.4.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

#### 65.4.1.2 Continuous mode (#s 2A & 2B)

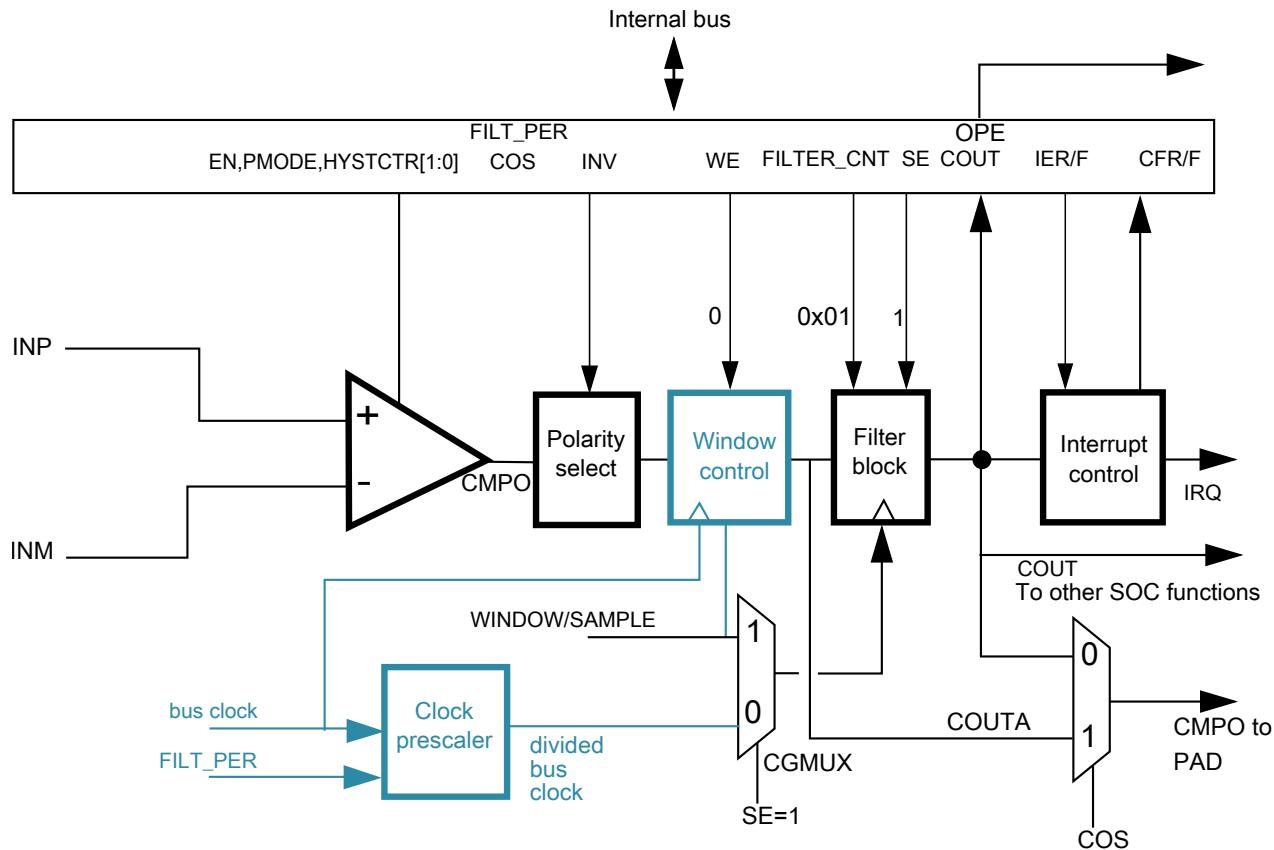

**Figure 65-3. Comparator operation in Continuous mode**

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unclocked mode. COUT and COUTA are identical.

For control configurations which result in disabling the filter block, see the [Filter Block Bypass Logic](#) diagram.

### 65.4.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

## Functional description

**Figure 65-4. Sampled, Non-Filtered (# 3A): sampling point externally driven**

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

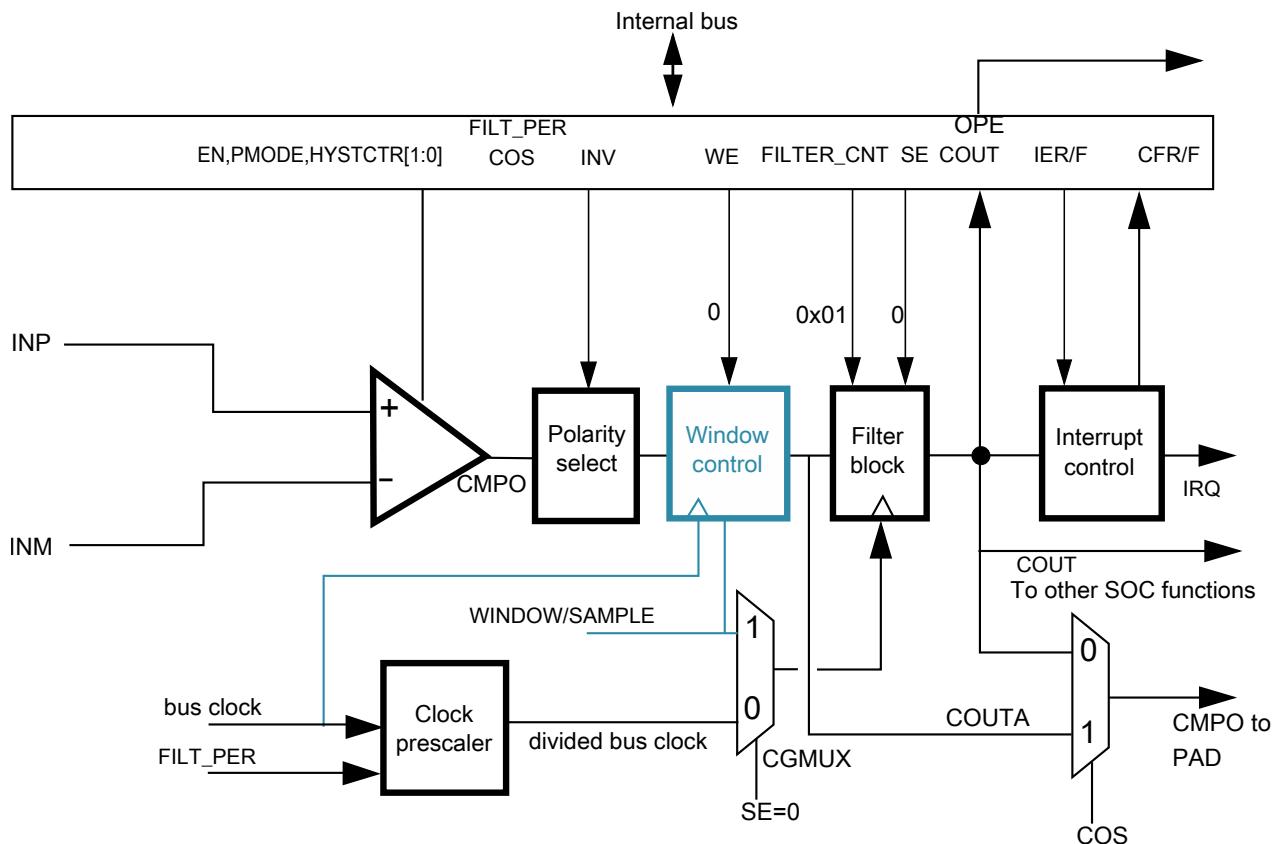

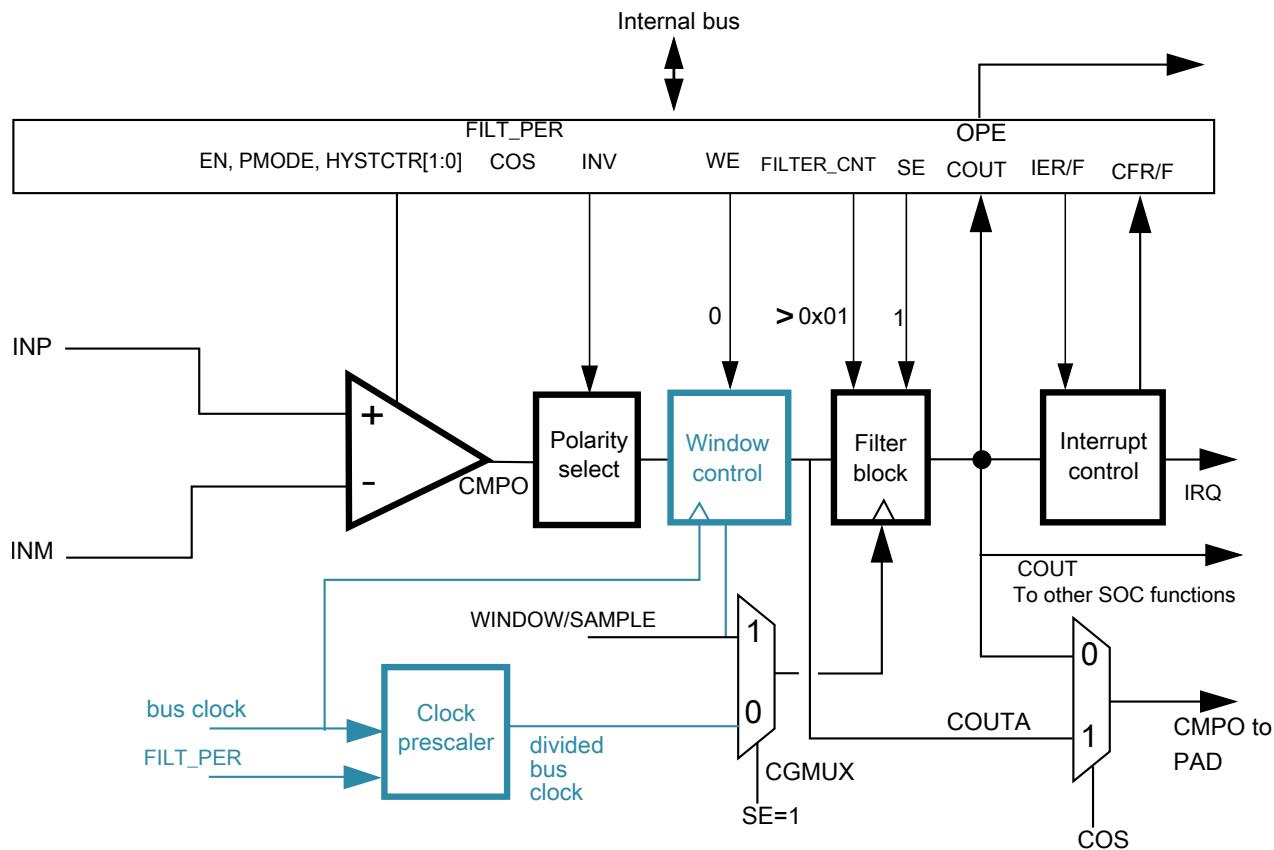

Figure 65-5. Sampled, Non-Filtered (# 3B): sampling interval internally derived

#### 65.4.1.4 Sampled, Filtered mode (#s 4A & 4B)

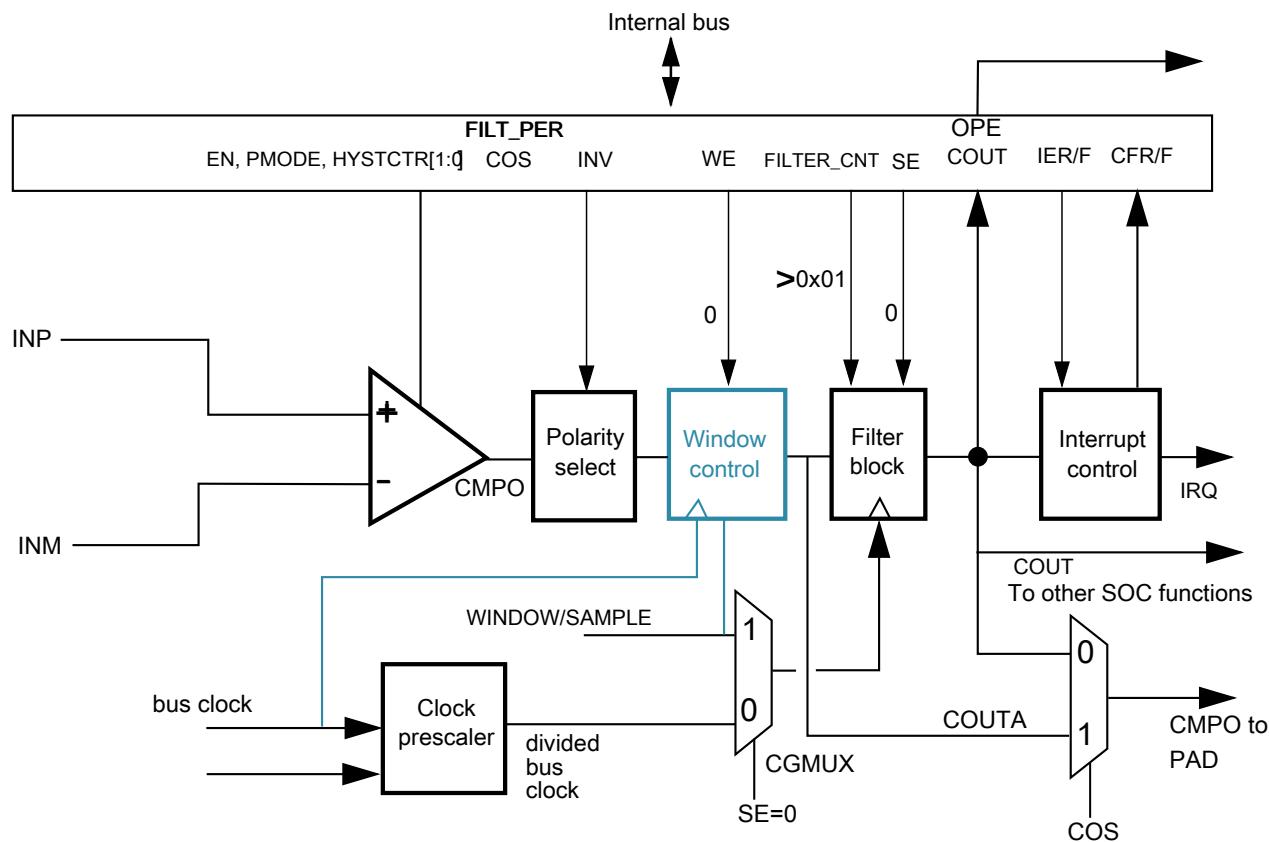

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, CR0[FILTER\_CNT]>1, which activates filter operation.

## Functional description

**Figure 65-6. Sampled, Filtered (# 4A): sampling point externally driven**

**Figure 65-7. Sampled, Filtered (# 4B): sampling point internally derived**

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, CR0[FILTER\_CNT]>1, which activates filter operation.

### 65.4.1.5 Windowed mode (#s 5A & 5B)

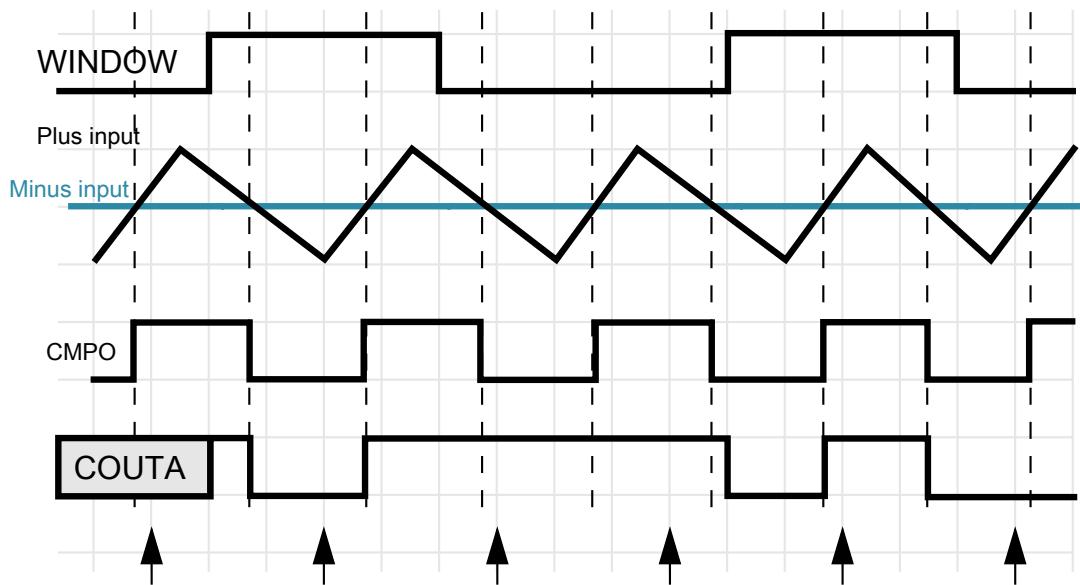

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

#### NOTE

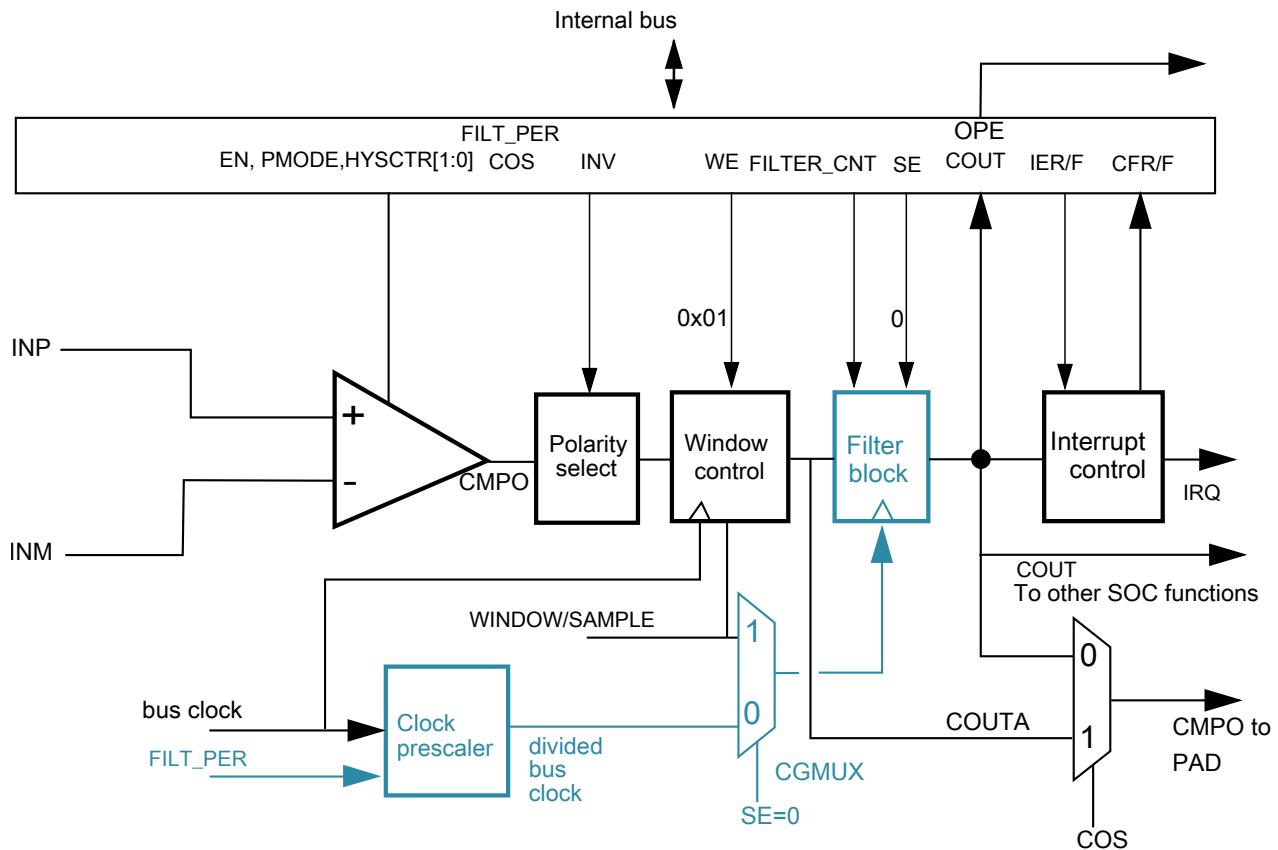

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

## Functional description

**Figure 65-8. Windowed mode operation**

**Figure 65-9. Windowed mode**

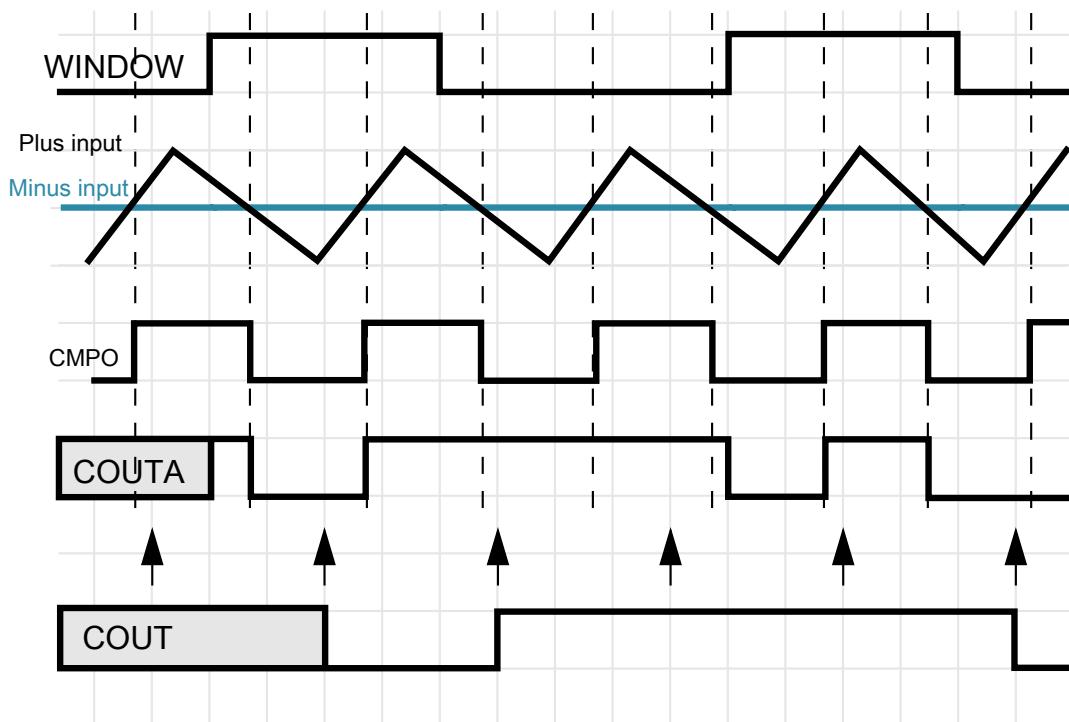

For control configurations which result in disabling the filter block, see [Filter Block Bypass Logic](#) diagram.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

#### 65.4.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in the figure "Windowed mode operation", and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

**Figure 65-10. Windowed/resampled mode operation**

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT\_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of CR0[FILTER\_CNT] must be 1.

### 65.4.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function +  $((CR0[FILTER_CNT] * FPR[FILT_PER]) + 1) * \text{bus clock}$  for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

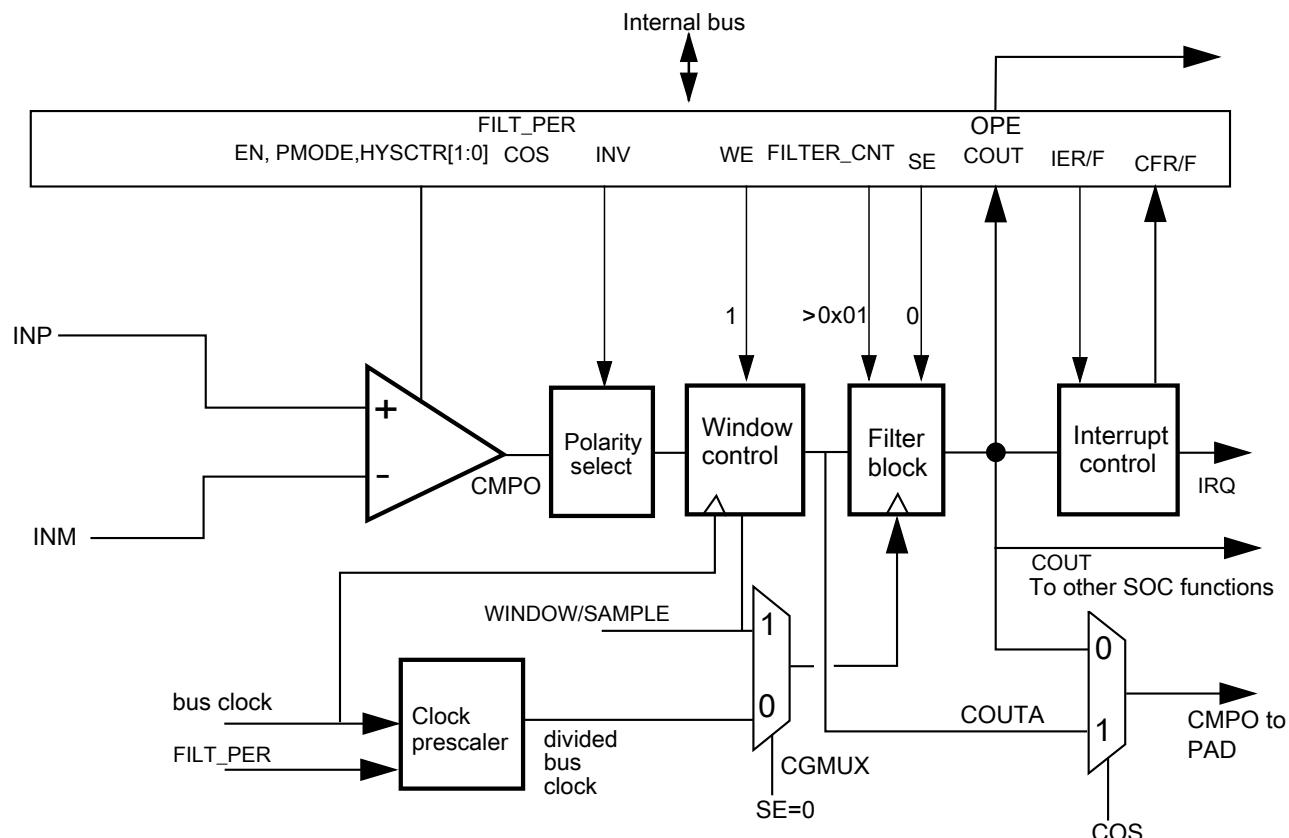

Figure 65-11. Windowed/Filtered mode

### 65.4.2 Power modes

#### 65.4.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.

### 65.4.2.2 Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

### 65.4.3 Startup and operation

A typical startup sequence is listed here.

- The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the [Low-pass filter](#).
- During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.
- When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

### 65.4.4 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT.

Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT\_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

#### 65.4.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER\_CNT] > 0x01 and
- Setting FPR[FILT\_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT\_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed. In other words, SCR[COUT] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT\_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

#### Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state.

Switching CR0[FILTER\_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed.

### 65.4.4.2 Latency issues

The value of FPR[FILT\_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER\_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER\_CNT].

The values of FPR[FILT\_PER] or SAMPLE period and CR0[FILTER\_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER\_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

**Table 65-3. Comparator sample/filter maximum latencies**

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation	Maximum latency <sup>1</sup>
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	0x00	X	Continuous Mode	$T_{PD}$
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FPR[FILT\_PER] * T_{per}) + T_{per}$
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	$T_{PD} + (CR0[FILTER\_CNT] * T_{SAMPLE}) + T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + T_{per}$
5A	1	1	0	0x00	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	0x00		$T_{PD} + T_{per}$
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	$T_{PD} + (FPR[FILT\_PER] * T_{per}) + 2T_{per}$
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	$T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + 2T_{per}$

1.  $T_{PD}$  represents the intrinsic delay of the analog component plus the polarity select logic.  $T_{SAMPLE}$  is the clock period of the external sample clock.  $T_{per}$  is the period of the bus clock.

## 65.5 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both.

The following table gives the conditions in which the interrupt request is asserted and deasserted.

When	Then
SCR[IER] and SCR[CFR] are set	The interrupt request is asserted
SCR[IEF] and SCR[CFF] are set	The interrupt request is asserted
SCR[IER] and SCR[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

## 65.6 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

## 65.7 Digital-to-analog converter

The figure found here shows the block diagram of the DAC module.

It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DCCR). Its supply reference source can be selected from two sources  $V_{in1}$  and  $V_{in2}$ . The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

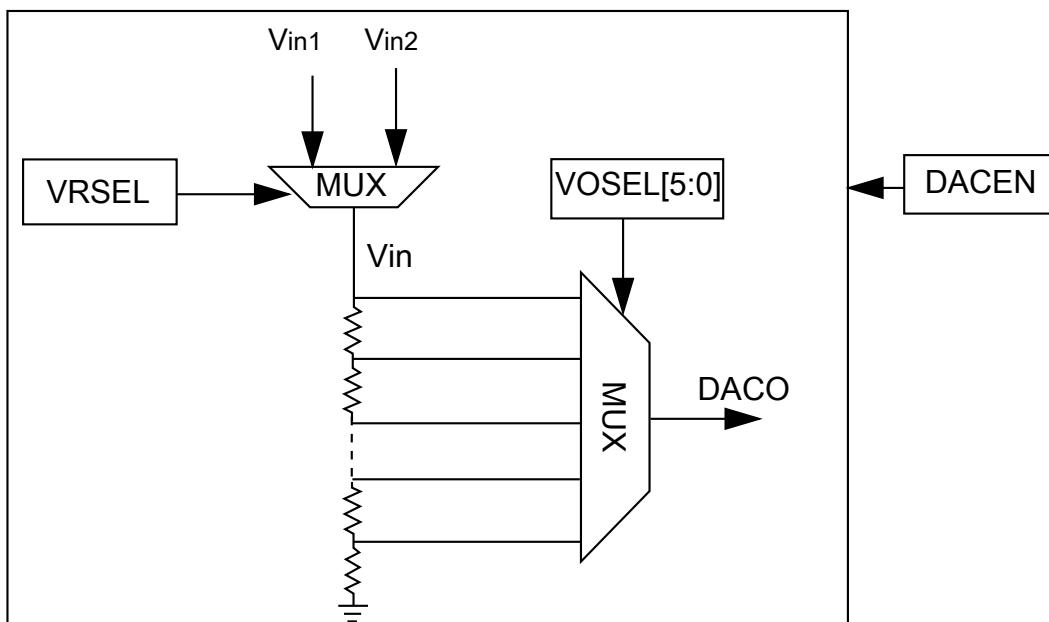

Figure 65-12. 6-bit DAC block diagram

## 65.8 DAC functional description

This section provides DAC functional description information.

### 65.8.1 Voltage reference source select

- $V_{in1}$  connects to the primary voltage source as supply reference of 64 tap resistor ladder
- $V_{in2}$  connects to an alternate voltage source

## 65.9 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

## 65.10 DAC clocks

This module has a single clock input, the bus clock.

## 65.11 DAC interrupts

This module has no interrupts.

$V_{REFH}$  /  $V_{REFL}$  are bonded to VDDA\_ADC\_3P3 / GND, on this device.

### 66.2 Overview

The analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

#### 66.2.1 Features

The features of the ADC are as follows:

- Configuration registers

- 32-bit, word aligned, byte enabled registers. (byte and halfword access is not supported)
- Linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy.
- Up to 10 ENOB (dedicated single ended channels)
- Up to 1MS/s sampling rate
- Up to 16 single-ended external analog inputs
- Single or continuous conversion (automatic return to idle after single conversion)
- Output Modes: (in right-justified unsigned format)
  - 12-bit
  - 10-bit
  - 8-bit
- Configurable sample time and conversion speed/power
- Conversion complete and hardware average complete flag and interrupt
- Input clock selectable from up to three sources
- Asynchronous clock source for lower noise operation with option to output the clock
- Selectable asynchronous hardware conversion trigger with hardware channel select
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Operation in low power modes for lower noise operation
- Hardware average function
- Self-calibration mode

## **66.2.2 ADC I/F block diagram**

The following diagram represents the ADC I/F block.

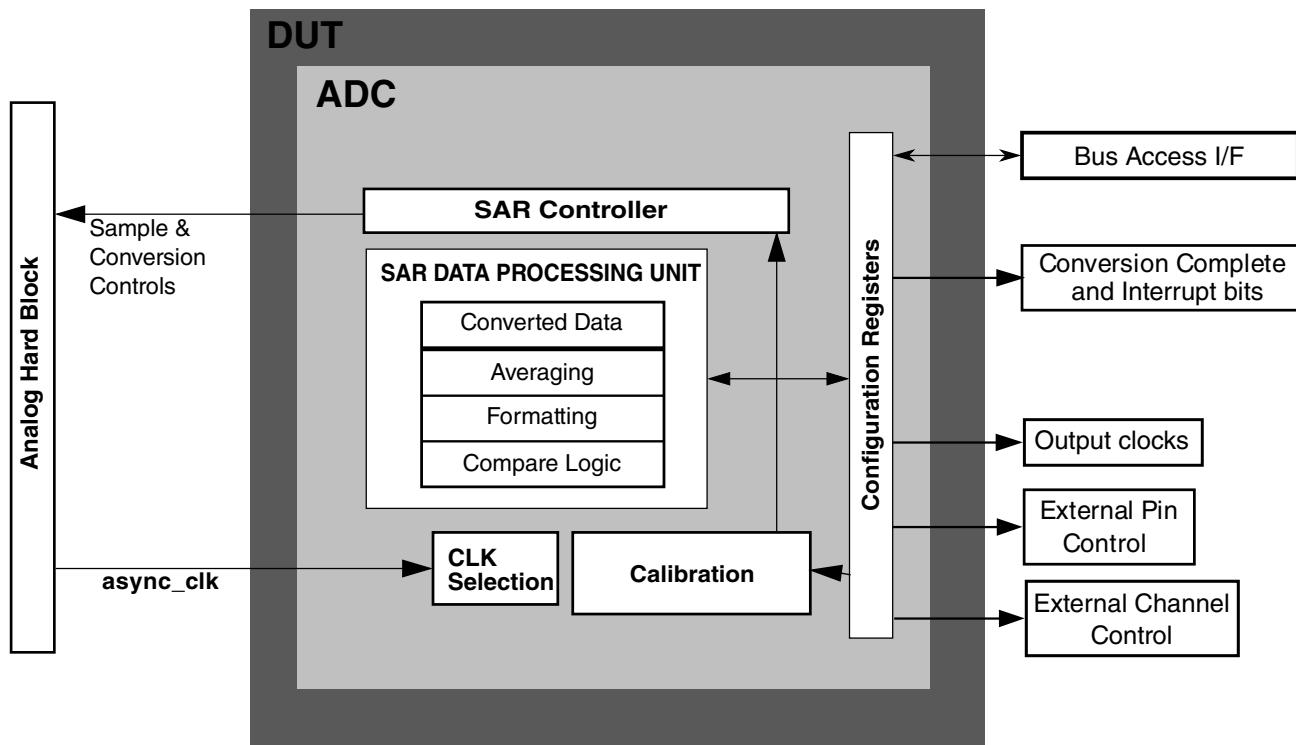

Figure 66-1. ADC I/F block diagram

### 66.2.3 ADC block diagram

The following figure shows a top-level block diagram of the ADC module.

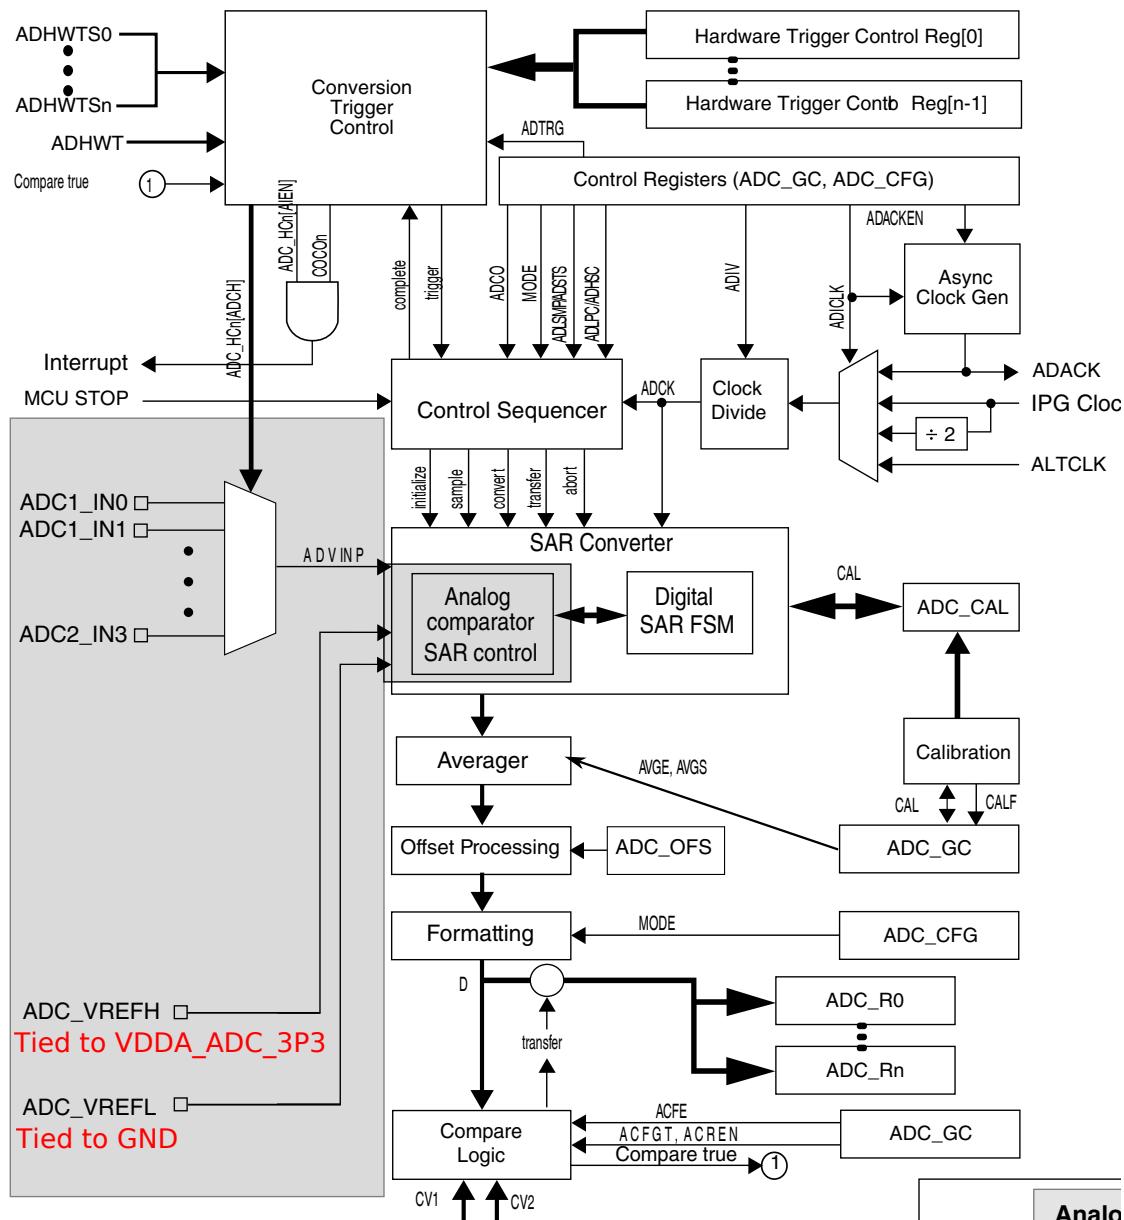

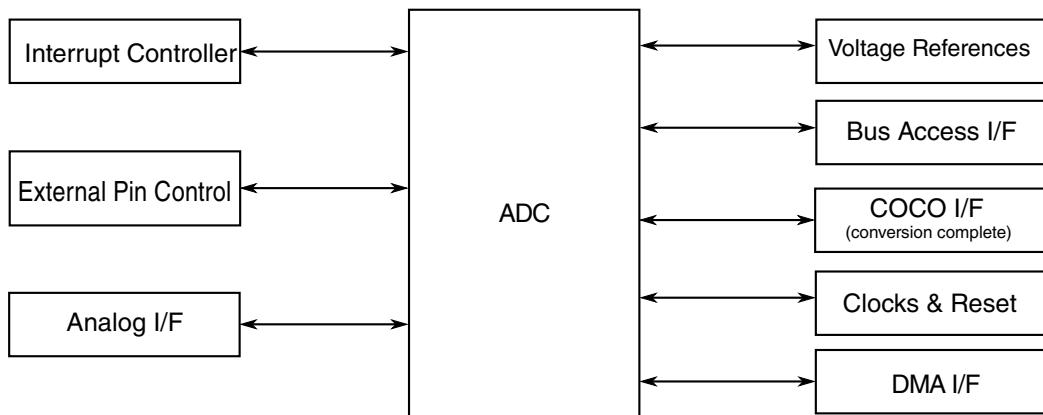

Figure 66-2. ADC block diagram

## 66.2.4 ADC module interface

The ADC is connected to many interfaces such as the clocks and reset, access bus, voltage references, interrupt controller, hardware triggers, ADC pin control, and analog I/F as shown in the following figure.

**Figure 66-3. ADC module interface**

## 66.2.5 Modes of Operation

By default, the ADC is in disabled mode. In this state, no conversion or other actions occur. All of the ADC control registers are accessible in this state through an access bus interface. To enable the ADC, required configurations should be done by programming the ADC configuration registers.

## 66.3 External Signals

The following table describes the external signals of ADC:

**Table 66-2. ADC external signals**

Signal	Description	Pad	Mode	Direction
ADC 1_IN0	Analog channel 1 input 0	GPIO_AD_B1_11 pin 21	-	I
ADC1_IN1	Analog channel 1 input 1	GPIO_AD_B0_12 pin 24	-	I
ADC1_IN2	Analog channel 1 input 2	GPIO_AD_B0_13 pin 25	-	I
ADC1_IN3	Analog channel 1 input 3	GPIO_AD_B0_14	-	I
ADC1_IN4	Analog channel 1 input 4	GPIO_AD_B0_15	-	I
ADC1_IN5	Analog channel 1 input 5	GPIO_AD_B1_00 pin 19	-	I
ADC1_IN6	Analog channel 1 input 6	GPIO_AD_B1_01 pin 18	-	I
ADC1_IN7	Analog channel 1 input 7	GPIO_AD_B1_02 pin 14	-	I

*Table continues on the next page...*

**Table 66-2. ADC external signals (continued)**

Signal	Description	Pad	Mode	Direction
ADC1_IN8	Analog channel 1 input 8	GPIO_AD_B1_03 pin 15	-	I
ADC1_IN9	Analog channel 1 input 9	GPIO_AD_B1_04 pin 40 (T4.1)	-	I
ADC1_IN10	Analog channel 1 input 10	GPIO_AD_B1_05 pin 41 (T4.1)	-	I
ADC1_IN11	Analog channel 1 input 11	GPIO_AD_B1_06 pin 17	-	I
ADC1_IN12	Analog channel 1 input 12	GPIO_AD_B1_07 pin 16	-	I
ADC1_IN13	Analog channel 1 input 13	GPIO_AD_B1_08 pin 22	-	I
ADC1_IN14	Analog channel 1 input 14	GPIO_AD_B1_09 pin 23	-	I
ADC1_IN15	Analog channel 1 input 15	GPIO_AD_B1_10 pin 20	-	I
ADC2_IN0	Analog channel 2 input 0	GPIO_AD_B1_11 pin 21	-	I
ADC2_IN1	Analog channel 2 input 1	GPIO_AD_B1_12 pin 38 (T4.1)	-	I
ADC2_IN2	Analog channel 2 input 2	GPIO_AD_B1_13 pin 39 (T4.1)	-	I
ADC2_IN3	Analog channel 2 input 3	GPIO_AD_B1_14 pin 26	-	I
ADC2_IN4	Analog channel 2 input 4	GPIO_AD_B1_15 pin 27	-	I
ADC2_IN5	Analog channel 2 input 5	GPIO_AD_B1_00 pin 19	-	I
ADC2_IN6	Analog channel 2 input 6	GPIO_AD_B1_01 pin 18	-	I
ADC2_IN7	Analog channel 2 input 7	GPIO_AD_B1_02 pin 14	-	I
ADC2_IN8	Analog channel 2 input 8	GPIO_AD_B1_03 pin 15	-	I
ADC2_IN9	Analog channel 2 input 9	GPIO_AD_B1_04 pin 40 (T4.1)	-	I
ADC2_IN10	Analog channel 2 input 10	GPIO_AD_B1_05 pin 41 (T4.1)	-	I
ADC2_IN11	Analog channel 2 input 11	GPIO_AD_B1_06 pin 17	-	I
ADC2_IN12	Analog channel 2 input 12	GPIO_AD_B1_07 pin 16	-	I
ADC2_IN13	Analog channel 2 input 13	GPIO_AD_B1_08 pin 22	-	I
ADC2_IN14	Analog channel 2 input 14	GPIO_AD_B1_09 pin 23	-	I

Table continues on the next page...

**Table 66-2. ADC external signals (continued)**

Signal	Description	Pad	Mode	Direction
ADC2_IN15	Analog channel 2 input 15	GPIO_AD_B1_10 pin 20	-	I

**NOTE**

The ADC input signals connect to GPIO. The GPIO default configuration is enabled for keeper. The keeper causes an undesired jump behavior in ADC. To avoid the problem, disable keeper before starting ADC. For detailed information about keeper, refer to the GPIO block.

## 66.4 Clocks

The following table describes the clock sources for ADC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 66-3. ADC Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock

## 66.5 Functional Description

There are three possible states which ADC module can be in:

1. Disabled State
2. Idle state
3. Performing conversions

**Disabled State:**

The ADC module is disabled during reset or stop mode (if internal clock is not selected as source of clock), or when the ADCH bits of the hardware control (ADC\_HCn) registers are all high.

**Idle State:**

The module is idle when a conversion has completed and another conversion has not been initiated. When idle and the asynchronous clock output enable is disabled (ADACKEN = 0), the module is in its lowest power state.

**Conversion State:**

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications the ADC module must be calibrated using the on chip calibration function. Calibration is recommended to be done after any reset.

When the conversion is completed, the result is placed in the data result registers (ADC\_Rn). The conversion complete flag (COCOn) field in the Hardware Status register is/are then set and an interrupt is generated, if the respective conversion complete interrupt has been enabled (ADC\_HCn[AIEN]=1).

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the compare value registers. The compare function is enabled by setting ACFE (ADC Compare Function Enable) in the ADC general control register.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting AVGE in the ADC general control register.

### **66.5.1 Clock Select and Divide Control**

The ADC digital module has two clock sources:

- IPG clock
- Internal clock (ADACK) is a dedicated clock used only by the ADC.

ADC digital block generates IPG clock/2 by internally dividing the IPG clock. The final clock is chosen from the following clocks.

- IPG clock
- IPG clock divided by 2
- ADACK

From the three clocks listed above, one is chosen depending on the configuration of ADICLK[1:0] bits of ADC\_CFG. This chosen clock is divided depending on the configuration of ADIV[1:0] bits of ADC\_CFG. The final generated clock is used as conversion clock for ADC.

ADICLK	Selected Clock Source
00	IPG clock
01	IPG clock divided by 2
10	Reserved
11	Asynchronous clock (ADACK)

- The IPG clock. This is the default selection following reset.
- The IPG clock divided by two. For higher IPG clock rates, this allows a maximum divide by 16 of the IPG clock using the ADIV bits.
- The asynchronous clock (ADACK). This clock is generated from a clock source within the ADC module. Conversions are possible using ADACK as the input clock source while the MCU is in stop mode.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADIV bits and can be divide-by 1, 2, 4, or 8.

### 66.5.2 Voltage Reference Selection

The ADC can be configured to use reference pairs as the reference voltages used for conversions ( $V_{REFSH}$  and  $V_{REFSL}$ ). Each pair contains a positive reference which must be between the minimum Ref Voltage High and  $V_{DDAD}$ , and a ground reference which must be at the same potential as  $V_{SSAD}$ . The pairs can be as follows:

- External ( $V_{REFH}$  and  $V_{REFL}$ )

These voltage references are selected by configuring ADC\_CFG[REFSEL].

### 66.5.3 Hardware Triggering and Channel Selection

The ADC module has a trigger input (known as Alternate Trigger) which provides asynchronous hardware conversion trigger when the ADTRG bit in ADC configuration register (ADC\_CFG) is set and any of the external hardware trigger select is high.

To be reliably captured, the Alternate Trigger pulse must be high for sufficient time to satisfy clocking requirement of capturing Flop and the external hardware trigger select event must be set for sufficient time before and after the positive edge of Alternate trigger pulse to meet the setup / hold requirement of capturing flop.

## Functional Description

If an external hardware trigger select event gets asserted during a conversion it must stay asserted until end of current conversion and remain set until the receipt of the an Alternate Trigger to initiate a new conversion.

When the Alternate Trigger source is available and hardware triggering is enabled (ADC\_CFG[ADTRG]=1), a conversion is initiated on the rising edge of the Alternate Trigger after a external hardware trigger select event has occurred.

If a conversion is in progress when a rising edge of a trigger occurs, the rising edge is ignored. In continuous conversion configuration, only the initial rising edge to launch continuous conversions is observed and until conversion gets aborted the ADC will continue to do conversions on the same ADC Hardware Trigger Control register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The channel selected for the conversion will depend on the settings of active Hardware Trigger register field ADC\_HCn[ADCH] of enabled external hardware trigger.

### NOTE

Asserting more than one external hardware trigger select signal at the same time will result in unknown results. To avoid this, only select one external hardware trigger select signal prior to the next intended conversion.

When the conversion is completed, the result is placed in the data registers associated with the external hardware trigger received (active trigger selects ADC\_Rn). The conversion complete flag associated with the external hardware trigger received (ADC\_HS[COCon]) is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled (ADC\_HCn[AIEN]=1).

## 66.5.4 Conversion Control

Conversions are performed as determined by ADC\_CFG[MODE] field.

Conversions can be initiated by either software or hardware triggers. In addition, the ADC can be configured for low power operation, long sample time, continuous conversion, hardware average, and automatic comparison of conversion results with predetermined values.

### 66.5.4.1 Initiating Conversions

A conversion is initiated:

- Following a write to ADC\_HC0 (with ADCHn bits not all 1's) and when a software triggered operation is selected (ADTRG=0).
- Following a hardware trigger event if hardware triggered operation is selected (ADTRG=1) and a external hardware trigger select event has occurred. The channel selected will depend on the active trigger select signal active selects ADC\_HC1; if neither is active the off condition is selected).

### Note

Selecting more than one external hardware trigger select signal (ext\_hwts[n]) prior to a conversion completion will generate unknown results. To avoid this, only select one hardware trigger select signal (ext\_hwts[n]) prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled (ADCO=1 in ADC\_GC register).

If continuous conversion is enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation (ADTRG=0), continuous conversions begin after ADC\_HC0 is written and continue until aborted. In hardware triggered operation(ADTRG=1 and one external hardware trigger select event has occurred), continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions is completed. In software triggered operation, conversions begin after ADC\_HC0 is written. In a hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions is also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

#### 66.5.4.2 Completing Conversions

A conversion is completed when the result of the conversion is transferred into the data result registers. (provided the compare function & hardware averaging is disabled), this is indicated by the setting of COCOn. If hardware averaging is enabled, COCOn sets only, if the last of the selected number of conversions is complete. If the compare function is enabled, COCOn sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then COCOn sets only if the last of the selected number of conversions is complete and the

compare condition is true. An interrupt is generated, if ADC\_HCn[AIEN] is high at the time that COCOn is set and if DMAEN is set, DMA request is asserted, if COCOn is set. Both the requests get deasserted when COCOn is low, cleared, which happens when data is read.

In all modes a blocking mechanism prevents a new result from overwriting previous data in ADC\_Rn, if the previous data is in the process of being read. When blocking is active (OVWREN=0 in ADC\_CFG), the conversion result data transfer is blocked, COCOn is not set, and the new result is lost. In all other cases of operation, when a conversion result data transfer is blocked, another conversion is initiated regardless of the state of ADCO (single or continuous conversions enabled).

### **Note**

If continuous conversions are enabled, the blocking mechanism could result in the loss of data occurring at specific timepoints. To avoid this issue, the data must be read in fewer cycles than an ADC conversion time, accounting for interrupt or software polling loop latency.

If single conversions are enabled, the blocking mechanism could result in several discarded conversions and excess power consumption. To avoid this issue, the data registers must not be read after initiating a single conversion until the conversion completes.

#### **66.5.4.3 Aborting Conversions**

Any conversion in progress is aborted when:

- The MCU enters stop mode with ADACK not enabled.
- In software trigger mode, write to ADC\_HC0 register, while ADC\_HC0 is actively (already) controlling a conversion, aborts the current conversion. Since none of the ADC\_HC1 - ADC\_HCn registers are used for software trigger operation, writing to any of them will not initiate a new conversion nor abort the software triggered active conversion.

- In hardware trigger mode, writing to any of the ADC\_HC0 - ADC\_HCn registers, while that specific register is actively controlling a conversion, will abort the current conversion.
- A write to any ADC register other than the ADC\_HC0: ADC\_HCn registers occurs. This indicates a mode of operation change has occurred and the current conversion is therefore invalid.

### Note

When a conversion is aborted, the contents of the data result registers, ADCRn are not altered. The data result registers continue to hold the values, transferred after the completion of the last successful conversion. If the conversion is aborted by a reset or stop (not operated with internal ADACK), ADCRn (data result register) return to their reset states.

#### 66.5.4.4 Power Control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source but the asynchronous clock output is disabled (ADACKEN=0), the ADACK clock generator will also remain in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled (ADACKEN=1), it will remain active regardless of the state of the ADC or the MCU power mode.

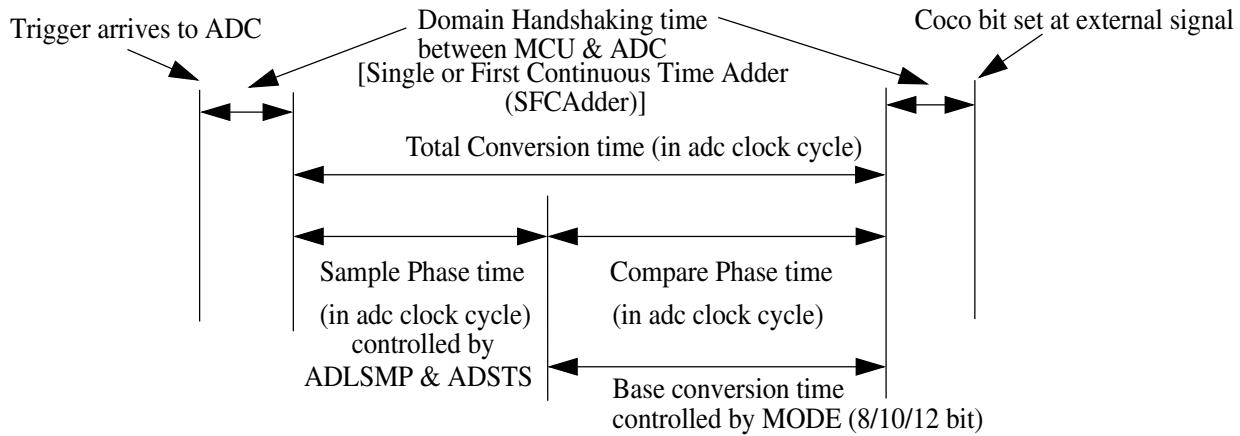

Power consumption when the ADC is active can be reduced by setting ADLPC.

#### 66.5.4.5 Sample Time and Total Conversion Time

The total conversion time depends upon the following:

- the sample phase time (as determined by ADLSMP and ADSTS bits in ADC\_CFG register),
- the compare phase time (determined by MODE bits)
- the frequency of the conversion clock ( $f_{ADCK}$ ).
- the MCU bus frequency (for Handshaking and selection of clock)

## Functional Description

**Figure 66-4. ADC conversion time details**

After the module becomes active, sampling of the input begins. ADLSMP and ADSTS decide the sample time duration. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADC\_Rn upon completion of the conversion algorithm.

If the bus frequency is less than the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed .

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by the ADICLK bits in ADC\_CFG register, and the divide ratio is specified by the ADIV bits.

The maximum total conversion time for all configurations is summarized in [Equation 1 on page 3414](#). Refer to [Table 66-4](#) through [Table 66-7](#) for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder})$$

**Equation 1. Equation of Conversion Time**

**Table 66-4. Single or First Continuous Time Adder (SFCAdder)**

ADACKEN	ADICLK	Single or First Continuous Time Adder (SFCAdder)
x	0x, 10	3 ADCK cycles (before starting of conversion) + 1ADCK (after end of conversion) + 2 bus clock cycles
1	11	3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles
0	11	1.5μs +

**Table 66-4. Single or First Continuous Time Adder (SFCAdder)**

ADACKEN	ADICLK	Single or First Continuous Time Adder (SFCAdder)
		3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles

**Table 66-5. Average Number Factor (AverageNum)**

AVGE	AVGS[1:0]	Average Number Factor (AverageNum)
0	xx	1
1	00	4
1	01	8
1	10	16
1	11	32

**Table 66-6. Base Conversion Time (BCT) (compare phase duration)**

Mode	Base Conversion Time (BCT) (compare phase duration)
8 bit	17 ADCK cycles
10 bit	21 ADCK cycles
12 bit	25 ADCK cycles

**Table 66-7. Long Sample Time**

ADLSMP	ADSTS	Long Sample Time Adder (LSTAdder)
0	00	3 ADCK cycles
0	01	5 ADCK cycles
0	10	7 ADCK cycles (default)
0	11	9 ADCK cycles
1	00	13 ADCK cycles
1	01	17 ADCK cycles
1	10	21 ADCK cycles
1	11	25 ADCK cycles

**Note**

The ADCK frequency must be between  $f_{ADCK}$  minimum and  $f_{ADCK}$  maximum to meet ADC specifications.

## 66.5.4.6 Conversion Time Examples

The following examples uses [Equation 1 on page 3414](#) and the information provided in tables [Table 66-4](#) through [Table 66-7](#).

### 66.5.4.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is: 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, ADLSMP=0,ADLSTS=10 and high speed conversion disabled. The conversion time for a single conversion is calculated by using [Equation 1 on page 3414](#) and the information provided in [Table 66-8](#) through [Table 66-10](#). The table below list the variables of [Equation 1 on page 3414](#).

**Table 66-8. Typical Conversion Time**

Variable	Time
SFCAdder	4 ADCK cycles + 2 bus clock cycles
AverageNum	1
BCT	21 ADCK cycles
LSTAdder	7

The resulting conversion time is generated using the parameters listed in [Table 66-8](#). So for Bus clock equal to 40 Mhz and ADCK equal to 40 Mhz the resulting conversion time is 0.85 us.

### 66.5.4.6.2 Long conversion time configuration

A configuration for long ADC conversion is: 12-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-8 ratio selected, and a bus frequency of 40 MHz, long sample time enabled (ADLSMP=1, ADSTS=11) and configured for longest adder and high speed conversion disabled. Average enabled for 32 conversions (AVGE=1, AVGS=11). The conversion time for this conversion is calculated by using equation on [Sample Time and Total Conversion Time](#) and the information provided in [Table 66-4](#) through [Table 66-7](#). The table below lists the variables of equation.

**Table 66-9. Typical Conversion Time**

Variable	Time
SFCAdder	4 ADCK cycles + 2 bus clock cycles
AverageNum	32
BCT	25 ADCK cycles
LSTAdder	25 ADCK cycles

The resulting conversion time is generated using the parameters listed in [Table 66-9](#). So for Bus clock equal to 40 Mhz and ADCK equal to 5 Mhz the resulting conversion time is 10.0226 us (AverageNum). This results in a total conversion time of 320.85 us.

#### 66.5.4.6.3 Short conversion time configuration

A configuration for short ADC conversion is: 8-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, long sample time disabled(ADLSMP=0, ADSTS=00) and high speed conversion enabled. The conversion time for this conversion is calculated by using the equation and the information provided in [Table 66-4](#) to [Table 66-7](#). The table below list the variables of equation.

**Table 66-10. Typical Conversion Time**

Variable	Time
SFCAdder	4 ADCK cycles + 2 bus clock cycles
AverageNum	1
BCT	17 ADCK cycles
LSTAdder	3 ADCK cycles

The resulting conversion time is generated using the parameters listed in [Table 66-10](#). So for Bus clock equal to 40Mhz and ADCK equal to 40Mhz the resulting conversion time is 650 ns.

#### 66.5.4.7 Hardware Average Function

The hardware average function can be enabled (AVGE=1) to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which select 4, 8, 16 or 32 conversions to be averaged. While the hardware average function is in progress the ADACT bit will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated after the selected number of conversions has been completed. When hardware averaging is selected the completion of a single conversion will not set the COCOn bit.

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, ADC\_Rn, and the COCOn bit is set. An ADC interrupt is generated upon the setting of COCOn if the respective ADC interrupt is enabled (AIENn=1).

## 66.5.5 Automatic Compare Function

The compare function can be configured to check if the result is less than or greater-than-or-equal-to a single compare value, or if the result falls within or outside a range determined by two compare values. The compare mode is determined by ACFGT, ACREN and the values in the compare value register (ADC\_CV). After the input is sampled and converted, the compare values (CV1 and CV2) are used as described in the table below. There are six compare modes as shown in the table below.

**Table 66-11. Compare Modes**

ACFGT	ACREN	CV1 relative to CV2	Function	Compare Mode Description
0	0	-	Less than threshold	Compare true if the result is less than the CV1 registers.
1	0	-	Greater than or equal to threshold	Compare true if the result is greater than or equal to CV1 registers.
0	1	Less than or equal	Outside range, not inclusive	Compare true if the result is less than CV1 <b>Or</b> the result is Greater than CV2
0	1	Greater than	Inside range, not inclusive	Compare true if the result is less than CV1 <b>And</b> the result is greater than CV2
1	1	Less Than or equal	Inside range, inclusive	Compare true if the result is greater than or equal to CV1 <b>And</b> the result is less than or equal to CV2
1	1	Greater than	Outside range, inclusive	Compare true if the result is greater than or equal to CV1 <b>Or</b> the result is less than or equal to CV2

With the ADC range enable bit set, ADCREN =1, if compare value 1(CV1 value) is less than or equal to the compare value 2 (CV2 value), setting ACFGT will select a trigger-if-inside-compare-range, inclusive-of-endpoints function. Clearing ACFGT will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than the CV2, setting ACFGT will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing ACFGT will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, COCOn is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, COCOn is not set and the conversion result data will not be transferred to the result register. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated upon the setting of COCOn if the respective ADC interrupt is enabled (ADC\_HCn[AIEN]=1).

## Note

The compare function can monitor the voltage on a channel while the MCU is in wait or stop3 mode. The ADC interrupt wakes the MCU when the compare condition is met.

### 66.5.6 Calibration Function

The ADC contains a self-calibration function that is required to achieve the specified accuracy. Calibration should be run or valid calibration values should be written after power up and system reset (as the calibration register will be reset on reset assertion) with specified settings before any conversion is initiated. The calibration function sets the calibration value at the end of running the full calibration sequence in ADC\_CAL register. The user must configure the ADC correctly prior to starting the calibration process, and must allow the process to run the full calibration sequence by checking the status of ADC\_GC[CAL] and ADC\_GS[CALF] so that the generated calibration value can be loaded.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, averaging, and the high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. The input channel, conversion mode, continuous function and compare function are all ignored during the calibration process.

To initiate calibration, the user sets the CAL bit and the calibration will automatically begin if the ADTRG bit = 0. If ADTRG = 1, the CAL bit will not get set and the calibration fail flag (CALF) will be set. While calibration is active, no ADC register can be written and no stop mode may be entered or the calibration routine will be aborted causing the CAL bit to clear and the CALF bit to set.

At the end of a calibration sequence the COCO[0] bit of the ADC\_HS register will be set. The ADC\_HCn[AIEN] bit can be used to allow an interrupt to occur at the end of a calibration sequence. If, at the end of calibration routine, the CALF bit is not set, the automatic calibration routine completed successfully.

To complete calibration, the user must follow the below procedure :

- Configure ADC\_CFG with actual operating values for maximum accuracy.
- Configure the ADC\_GC values along with CAL bit
- Check the status of CALF bit in ADC\_GS and the CAL bit in ADC\_GC
- When CAL bit becomes '0' then check the CALF status and COCO[0] bit status

When complete the user may reconfigure and use the ADC as desired.

A second calibration may also be performed if desired by clearing and again setting the CAL bit

Overall the calibration routine may take as many as 14000 ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen.

### **66.5.7 User Defined Offset Function**

The ADC Offset Correction Register (ADC\_OFS) contains the user configured offset value. This register is 13 bit wide. The value in MSB (13th bit ) is the operation bit, if this bit is ‘0’ then the value in rest 12 bit is added with the converted result value to generate final result to be loaded into ADC\_Rn and if this bit is ‘1’ then this field is subtracted from converted value to generate final Result (ADC\_Rn). If the Final result is above the maximum or below the minimum result value, it is forced to the appropriate limit for the current mode of operation. Forced to 0xFFFF if over and 0x0000 if lower for 12 bit mode.

The offset value has no effect during calibration on the final result.

The formatting of the ADC Offset Register is different from the Data Result Registers (ADC\_Rn) to preserve the resolution of the value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8b single-ended mode, the bits OFS[11:4] are subtracted from D[7:0] when bit OFS[12] (sign bit) is ‘1’ ; indicates subtraction and bits OFS[4:0] are ignored. For 12b single-ended mode, bits OFS[11:0] are directly subtracted from the conversion result data CDATA[11:0] when OFS[12] (sign bit) is ‘1’. The similar is the addition operation when OFS[12](sign bit) is 0.

ADC\_OFS is manually set according to user requirements after the self calibration sequence is done (CAL is cleared). The user have to write ADC\_OFS with desired value.

#### **NOTE**

There is an effective limit to the values of Offset that can be set by the user. If the magnitude of the offset is too great the results of the conversions will cap off at the limits.

The offset function may be employed by the user to remove application offsets or DC bias values. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value.

For applications which may change the offset repeatedly during operation, it is recommended to store the initial offset value in flash so that it can be recovered and added to any user offset adjustment value and the sum stored in the ADC\_OFS registers.

### 66.5.8 MCU Wait Mode Operation

Wait mode is a **lower power-consumption standby mode** from which **recovery is fast** because **the clock sources remain active**. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in wait mode.

A conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from wait mode.

If the compare and hardware averaging functions are disabled, a conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from wait mode if the respective ADC interrupt is enabled (ADC\_HCn[AIEN]=1).

If the hardware averaging function is enabled the COCOn will set (and generate an interrupt if enabled) when the selected number of conversions are complete.

If the compare function is enabled the COCOn will set (and generate an interrupt if enabled) only if the compare conditions are met.

If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from wait mode unless a new conversion is initiated by the hardware trigger.

### 66.5.9 MCU Stop Mode Operation

Stop mode is a low power-consumption standby mode during which most or all clock sources on the MCU are disabled. Stop mode is entered when stop indication comes from the MCU.

### 66.5.9.1 Stop Mode With ADACK Disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its idle state. The contents of the ADC registers, including ADC\_Rn are unaffected by stop mode. After exiting from stop mode, a software or hardware trigger is required to resume conversions.

### 66.5.9.2 Stop Mode With ADACK Enabled

If ADACK is selected as the conversion clock, the ADC continues operation during stop mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during stop mode.

If a conversion is in progress when the MCU enters stop mode, it continues until completion. Conversions can be initiated while the MCU is in stop mode by means of the hardware trigger or if continuous conversions are enabled.

A conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from stop mode :

#### Note

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this scenario, software should ensure the conversion result data transfer blocking mechanism (discussed in [Completing Conversations](#)) is cleared when entering stop and continuing ADC conversions.

## 66.6 Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. User can configure the module for 8, 10, 12 bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options.

### 66.6.1 ADC Module Initialization Example

This section describes the initialization sequence along with pseudo-code.

### 66.6.1.1 Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

- Calibrate the ADC by following the calibration instructions in [Calibration Function](#)
- Update the configuration register (ADC\_CFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- Update General control register (ADC\_GC) to select whether conversions will be continuous or completed only once (ADCO) and to select whether to perform hardware averaging, etc.
- Update Trigger control register (ADC\_HCn) to select the conversion trigger (hardware or software, i.e. configure ADTRG bit) and compare function options, if enabled.

### 66.6.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

#### ADC\_CFG

Bit 7	ADLPC	1	Configures for low power (lowers maximum clock speed).
Bit 6:5	ADIV	00	Sets the ADCK to the input clock $\div$ 1.
Bit 4	ADLSMP	1	Configures for long sample time.
Bit 3:2	MODE	10	Sets mode at 10-bit conversions.
Bit 1:0	ADICLK	00	Selects bus clock as input clock source.

#### ADC\_GC

Bit 7	CAL	0	Flag indicates if a conversion is in progress.
Bit 6	ADCO	0	Software trigger selected.
Bit 5	AVGE	0	Compare function disabled.
Bit 4	ACFE	0	Compare function disabled.
Bit 3	ACFGT	0	Not used in this example.
Bit 2	ACREN	0	Not used in this example.
Bit 1	DMAEN	0	Not used in this example.
Bit 0	ADACKEN	0	Not used in this example.

#### ADC\_HC0

## Application Information

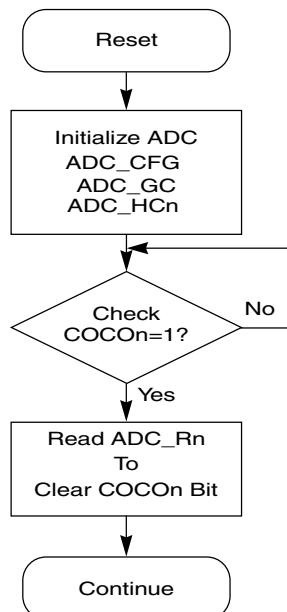

Bit 7      AIEN    1      Conversion complete interrupt enabled.  
Bit 4:0    ADCH    00001    Input channel 1 selected as ADC input channel.

### ADC\_R0

Holds results of conversion. Read high byte (ADCRHA) before low byte (ADCRILA) so that conversion data cannot be overwritten with data from the next conversion.

### ADC\_CV

Holds compare values when compare function enabled.

**Figure 66-5. Initialization Flowchart for Example**

## 66.7 Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

### 66.7.1 Sources of Error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

### 66.7.1.1 Sampling Error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately  $7\text{k}\Omega$  and input capacitance of approximately  $1.3\text{ pF}$ , sampling to within  $1/4\text{LSB}$  (at 12-bit resolution) can be achieved within the nominal sample window (6 cycles @ 40 MHz maximum ADCK frequency) provided the resistance of the external analog source ( $R_{AS}$ ) is kept below  $4\text{ k}\Omega$ .

Higher source resistances or higher-accuracy sampling is possible by setting ADLSMP and changing the ADSTS bits (to increase the sample window) or decreasing ADCK frequency to increase sample time.

### 66.7.1.2 Pin Leakage Error

Leakage on the I/O pins can cause conversion error if the external analog source resistance ( $R_{AS}$ ) is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $V_{DDAD}/(2^N * I_{LEAK})$  for less than  $1/4\text{LSB}$  leakage error ( $N = 8$  in 8-bit, 10 in 10-bit or 12 in 12-bit mode).

### 66.7.1.3 Noise-Induced Errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a  $0.1\text{ }\mu\text{F}$  low-ESR capacitor from  $V_{REFH}$  to  $V_{REFL}$ .
- There is a  $0.1\text{ }\mu\text{F}$  low-ESR capacitor from  $V_{DDAD}$  to  $V_{SSAD}$ .
- If inductive isolation is used from the primary supply, an additional  $1\text{ }\mu\text{F}$  capacitor is placed from  $V_{DDAD}$  to  $V_{SSAD}$ .
- $V_{SSAD}$  (and  $V_{REFL}$ , if connected) is connected to  $V_{SS}$  at a quiet point in the ground plane.
- Operate the MCU in wait or stop mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion.

- For software triggered conversions, immediately follow the write to ADCSC1 with a wait instruction or stop instruction.
- For stop mode operation, select ADACK as the clock source. Operation in stop reduces V<sub>DD</sub> noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive V<sub>DD</sub> noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu$ F capacitor (CAS) on the selected input channel to V<sub>REFL</sub> or V<sub>SS</sub> (this improves noise issues, but affects the sample rate based on the external analog source resistance).
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

#### 66.7.1.4 Code Width and Quantization Error

##### Note

This will remain the same as long as the result is rounded for 8 and 10-bit modes. If the result is truncated in 8/10b modes then they will match 12b mode where the quantization error is -1 to 0.

The ADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10 or 12), defined as 1LSB, is:

$$\text{1lsb} = (V_{\text{REFH}} - V_{\text{REFL}}) / 2^N$$

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual

transfer function. Therefore, the quantization error will be  $\pm 1/2$  lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

For 12-bit conversions the code transitions only after the full code width is present, so the quantization error is -1 lsb to 0 lsb and the code width of each step is 1 lsb.

### 66.7.1.5 Linearity Errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error ( $E_{ZS}$ ) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width (1/2 lsb in 8-bit or 10-bit modes and 1 lsb in 12-bit mode). If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 lsb) is used.
- Full-scale error ( $E_{FS}$ ) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width (1.5 lsb in 8-bit or 10-bit modes and 1LSB in 12-bit mode). If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1LSB) is used.
- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

### 66.7.1.6 Code Jitter, Non-Monotonicity, and Missing Codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.

## Memory map and register definition

Code jitter is when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate (between two codes) for a range of input voltages around the transition voltage. This range is normally around  $\pm 1/2$  lsb in 8-bit or 10-bit mode, or around 2 lsb in 12-bit mode, and increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in [Noise-Induced Errors](#) reduces this error.

Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage. Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

## 66.8 Memory map and register definition

The ADC-Digital contains 32-bit, word aligned, byte enables registers; byte or half word access are not supported. All configuration registers are accessible via 32-bit access bus Interface. Write access to reserved locations have no impact while read access to reserved locations always return 0.

### NOTE

No protection or indication mechanism is available (for example, 32-bit access starting with address offset value 0x01 or 0x02 or 0x03). The ADC does not check for correctness of the programmed values in the registers and the programmer must ensure that correct values are being written.

### 66.8.1 Control register for hardware triggers (ADCx\_HC0)

ADC\_HC0 can be used for both software and hardware trigger mode. Other ADC\_HCn ( $n = 1\dots$ ) are for use only in hardware trigger mode. The ADC\_HC0 to ADC\_HCn ( $n = 1\dots$ ) registers have identical fields, and are used to control ADC operation. At any one point in time, only one of the ADC\_HC0 to ADC\_HCn ( $n = 1\dots$ ) registers is actively controlling ADC conversions. Updating ADC\_HC0 while ADC\_HCn ( $n = 1\dots$ ) is actively controlling a conversion is allowed (and vice-versa for any of the ADC\_HCn ( $n = 1\dots$ ) registers). Writing ADC\_HC0 while ADC\_HC0 is actively controlling a conversion aborts the current conversion. In software trigger mode (ADTRG=0), writes to ADC\_HC0 subsequently initiates a new conversion (if the ADCH bits are equal to a value other than all 1s). Similarly, writing any of the ADC\_HCn ( $n = 1\dots$ ) registers while that specific ADC\_HCn register is actively controlling a conversion aborts the current conversion. ADC\_HCn ( $n = 1\dots$ ) register is not used for software trigger operation and therefore writes to any of them do not initiate a new conversion.

## 66.8.2 Control register for hardware triggers (ADCx\_HCn)

ADC\_HC $n$  ( $n = 1\dots$ ) are for use only in hardware trigger mode. The ADC\_HC0 to ADC\_HC $n$  registers have identical fields, and are used to control ADC operation. At any one point in time, only one of the ADC\_HC0 to ADC\_HC $n$  registers is actively controlling ADC conversions. Updating ADC\_HC0 while ADC\_HC $n$  is actively controlling a conversion is allowed (and vice-versa for any of the ADC\_HC $n$  registers). Writing any of the ADC\_HC $n$  registers while that specific ADC\_HC $n$  register is actively controlling a conversion aborts the current conversion. Any of the ADC\_HC $n$  ( $n = 1\dots$ ) registers are not used for software trigger operation and therefore writes to any of them do not initiate a new conversion.

**ADCx\_HS field descriptions**

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 COCO7	See description for COCO1.
6 COCO6	See description for COCO1.
5 COCO5	See description for COCO1.
4 COCO4	See description for COCO1.
3 COCO3	See description for COCO1.
2 COCO2	See description for COCO1.
1 COCO1	<p>Conversion Complete Flag</p> <p>See detailed description in COCO0, but for use only in hardware trigger mode.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>In the hardware trigger mode, when trigger comes from TSC, COCO bit can be cleared by writing TSC register. When other ADC_ETC trigger sources work as ADC hardware trigger, COCO bit is cleared automatically when each phase is done.</li> </ul>
0 COCO0	<p>Conversion Complete Flag</p> <p>The COCOOn flag is a read-only bit that is set each time a conversion is completed when the compare function is disabled (ADC_GC[ACFE]=0) and the hardware average function is disabled (ADC_GC[AVGE]=0). When the compare function is enabled (ADC_GC[ACFE]=1), the COCOOn flag is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled (ADC_GC[AVGE]=1), the COCOOn flag is set upon completion of the selected number of conversions (determined by the ADC_CFG[AVGS] field). The COCO0 flag will also set at the completion of a Calibration and Test sequence. A COCOOn bit is cleared when the respective ADC_HCn is written or when the respective ADC_Rn is read.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>In the hardware trigger mode, when trigger comes from TSC, COCO bit can be cleared by writing TSC register. When other ADC_ETC trigger sources work as ADC hardware trigger, COCO bit is cleared automatically when each phase is done.</li> <li>In the software trigger mode, COCO0 bit is cleared when ADC_HC0 is written or when ADC_R0 is read.</li> </ul>

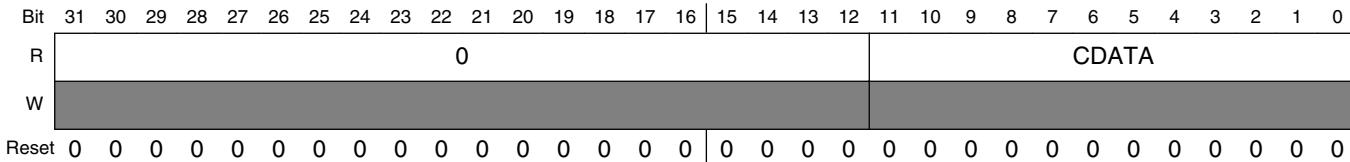

### 66.8.4 Data result register for HW triggers (ADCx\_R0)

Contains the result of an ADC conversion of the channel selected by the respective hardware trigger and channel control register (ADC\_HC0:ADC\_HCn). For every ADC\_HC0:ADC\_HCn status and channel control register, there is a respective ADC\_R0:ADC\_Rn data result register. Unused bits in the ADC\_Rn register are cleared in unsigned right justified modes. For example when configured for 10-bit single-ended mode, D[31:10] are cleared. The table below describes the behavior of the data result registers in the different modes of operation.

**Table 66-12. Data Result Register Description**

Conversion Mode	Data Result Register bits																Format
	D31	D30	...	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

### ADCx\_CFG field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 OVWREN	Data Overwrite Enable  Controls the overwriting of the next converted Data onto the existing (previous) unread data into the Data result register.  1 Enable the overwriting. 0 Disable the overwriting. Existing Data in Data result register will not be overwritten by subsequent converted data.
15–14 AVGS	Hardware Average select  Determines how many ADC conversions will be averaged to create the ADC average result. This functionality is activated when ADC_GC[AVGE] = 1.  00 4 samples averaged 01 8 samples averaged 10 16 samples averaged 11 32 samples averaged
13 ADTRG	Conversion Trigger Select  Selects the type of trigger used for initiating a conversion. Two types of trigger are selectable: software trigger and hardware trigger. When software trigger is selected, a conversion is initiated following a write to ADC_HC0. When hardware trigger is selected, a conversion is initiated following the assertion of a pulse on Alternate Hardware trigger input along with the assertion of the enable of respective the hardware Triggers input.

Table continues on the next page...

## ADCx\_CFG field descriptions (continued)

Field	Description
	<p>0 Software trigger selected 1 Hardware trigger selected</p>
12–11 REFSEL	<p>Voltage Reference Selection Selects the voltage reference source used for conversions.</p> <p>00 Selects VREFH/VREFL as reference voltage. 01 Reserved 10 Reserved 11 Reserved</p>
10 ADHSC	<p>High Speed Configuration This bit configures the ADC for high speed operation. The internal ADC clock is higher than normal.</p> <p>0 Normal conversion selected. 1 High speed conversion selected.</p>
9–8 ADSTS	<p>Defines the <b>total</b> sample time duration <b>in number of full cycles</b>. This has two modes, short and long. When long sample time is selected (ADLSMP=1) this works for long sample time otherwise this works for short sample. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required.</p> <p><b>NOTE:</b> The actual sampling of capacitors happens 1/2 cycle less than the above values to prevent leakage of charge during switching from sample to conversion phase for better accuracy.</p> <p>00 Sample period (ADC clocks) = 3 if ADLSMP=0b Sample period (ADC clocks) = 13 if ADLSMP=1b 01 Sample period (ADC clocks) = 5 if ADLSMP=0b Sample period (ADC clocks) = 17 if ADLSMP=1b 10 Sample period (ADC clocks) = 7 if ADLSMP=0b Sample period (ADC clocks) = 21 if ADLSMP=1b 11 Sample period (ADC clocks) = 9 if ADLSMP=0b Sample period (ADC clocks) = 25 if ADLSMP=1b</p>
7 ADLPC	<p>Low-Power Configuration Puts the ADC hard block into low power mode and reduces the comparator enable period by controlling its timing in the SAR controller block towards the analog hard block.</p> <p>The signal indicating low power mode to the Analog block is asserted when this bit is set.</p> <p>0 ADC hard block not in low power mode. 1 ADC hard block in low power mode.</p>
6–5 ADIV	<p>Clock Divide Select Selects the divide ratio used by the ADC to generate the internal clock ADCK.</p> <p>00 Input clock 01 Input clock / 2 10 Input clock / 4 11 Input clock / 8</p>

Table continues on the next page...

**ADCx\_CFG field descriptions (continued)**

Field	Description
4 ADLSMP	<p>Long Sample Time Configuration</p> <p>Selects between different sample times based on the ADC_CFG[ADSTS] field. This bit adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. If high conversion rates are not required, longer sample times can also be used to lower overall power consumption when continuous conversions are enabled. When ADLSMP=1, the Long Sample Time mode is selected and the time is defined by ADSTS[1:0] of the ADC_CFG register.</p> <p>0 Short sample mode. 1 Long sample mode.</p>
3–2 MODE	<p>Conversion Mode Selection</p> <p>Used to set the ADC resolution mode.</p> <p>00 8-bit conversion 01 10-bit conversion 10 12-bit conversion 11 Reserved</p>
ADICLK	<p>Input Clock Select</p> <p>Selects the input clock source to generate the internal clock ADCK.</p> <p>00 IPG clock 01 IPG clock divided by 2 10 Reserved 11 Asynchronous clock (ADACK)</p>

### 66.8.7 General control register (ADCx\_GC)

Controls the calibration, continuous convert, hardware averaging functions, conversion active, hardware/software trigger select, compare function and voltage reference select of the ADC module.

Address: Base address + 48h offset

#### ADCx\_GC field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 CAL	Calibration  CAL begins the calibration sequence when set. This bit stays set while the calibration is in progress and is cleared when the calibration sequence is complete. The ADC_GS[CALF] bit must be checked to determine the result of the calibration sequence. After it has started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and the ADC_GS[CALF] bit will set. Setting the CAL bit will abort any current conversion.
6 ADCO	Continuous Conversion Enable  Enables continuous conversions.  0 One conversion or one set of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion. 1 Continuous conversions or sets of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion.
5 AVGE	Hardware average enable  Enables the hardware average function of the ADC.  0 Hardware average function disabled 1 Hardware average function enabled

Table continues on the next page...

**ADCx\_GC field descriptions (continued)**

Field	Description
4 ACFE	<p>Compare Function Enable</p> <p>Enables the compare function.</p> <p>0 Compare function disabled 1 Compare function enabled</p>
3 ACFGT	<p>Compare Function Greater Than Enable</p> <p>Configures the compare function to check the conversion result relative to the compare value register (ADC_CV) based upon the value of ACREN (bit 2 in ADC_GC register). The ACFE bit must be set for ACFGT to have any effect.</p> <p>0 Configures "Less Than Threshold, Outside Range Not Inclusive and Inside Range Not Inclusive" functionality based on the values placed in the ADC_CV register. 1 Configures "Greater Than Or Equal To Threshold, Outside Range Inclusive and Inside Range Inclusive" functionality based on the values placed in the ADC_CV registers.</p>
2 ACREN	<p>Compare Function Range Enable</p> <p>Configures the compare function to check the conversion result of the input being monitored is either between or outside the range formed by the compare values in register (ADC_CV) determined by the value of ACFGT. The ACFE bit must be set for ACFGT to have any effect.</p> <p>0 Range function disabled. Only the compare value 1 of ADC_CV register (CV1) is compared. 1 Range function enabled. Both compare values of ADC_CV registers (CV1 and CV2) are compared.</p>
1 DMAEN	<p>DMA Enable</p> <p>Enables the DMA logic.</p> <p>0 DMA disabled (default) 1 DMA enabled</p>
0 ADACKEN	<p>Asynchronous clock output enable</p> <p>Enables the ADC's asynchronous clock source and the clock source output regardless of the conversion and input clock select (ADC_CFG[ADICLK]) settings of the ADC. Based on MCU configuration, the asynchronous clock may be used by other modules (see module introduction section). Setting this bit allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced since the ADACK clock is already operational.</p> <p>0 Asynchronous clock output disabled; Asynchronous clock only enabled if selected by ADICLK and a conversion is active. 1 Asynchronous clock and clock output enabled regardless of the state of the ADC</p>

## 66.8.8 General status register (ADCx\_GS)

Controls the calibration, continuous convert, hardware averaging functions, conversion active, hardware/software trigger select, compare function and voltage reference select of the ADC module.

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### ADCx\_GS field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2 AWKST	Asynchronous wakeup interrupt status  Holds the status of asynchronous interrupt status that occurred during stop mode. This bit is set when ipg_stop is deasserted and ipg_clk has started. It is cleared by writing ‘1’ to it. Clearing this bit also deasserts the Asynchronous interrupt to CPU.  1 Asynchronous wake up interrupt occurred in stop mode. 0 No asynchronous interrupt.
1 CALF	Calibration Failed Flag

Table continues on the next page...

**ADCx\_GS field descriptions (continued)**

Field	Description
	<p>Displays the result of the calibration sequence. The calibration sequence will fail if Hardware Trigger is selected (i.e. ADC_CFG[ADTRG] = 1), or any ADC register is written, or any stop mode is entered before the calibration sequence completes. The CALF bit is cleared by writing a 1 to it.</p> <p>0 Calibration completed normally. 1 Calibration failed. ADC accuracy specifications are not guaranteed.</p>
0 ADACT	<p>Conversion Active</p> <p>Indicates that a conversion or hardware averaging is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted.</p> <p>0 Conversion not in progress. 1 Conversion in progress.</p>

**66.8.9 Compare value register (ADCx\_CV)**

Contains compare values used to compare with the conversion result when the compare function is enabled (ADC\_GC[ACFE]=1). The compare values are right justified.

Therefore, the compare function only uses the compare value register bits that are related to the ADC mode of operation. (e.g. in 8 bit mode, CV1 = ADC\_CV[7:0] and CV2 = ADC\_CV[23:16], similarly in 10 bit mode, CV1 = ADC\_CV[9:0] and CV2 = ADC\_CV[25:16] etc.) The compare value 2 in this register is utilized only when the compare range function is enabled (ADC\_GC[ACREN]=1).

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ADCx\_CV field descriptions**

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 CV2	<p>Compare Value 2</p> <p>Contains a compare value used to compare with the conversion result when the compare function and compare range function are enabled (ADC_GC[ACFE]=1, ADC_GC[ACREN]=1).</p>
15–12 Reserved	This read-only field is reserved and always has the value 0.
CV1	<p>Compare Value 1</p> <p>Contains a compare value used to compare with the conversion result when the compare function is enabled (ADC_GC[ACFE]=1).</p>

### 66.8.10 Offset correction value register (ADCx\_OFs)

Contains the user-defined offset error correction value. This register is 13 bits wide. The value in the most significant bit (13th bit) is the operation bit. If this bit is ‘0’ then the value in the other 12 bits is added with the converted result value to generate final result to be loaded into ADC\_Rn; if this bit is ‘1’ then this field is subtracted from converted value to generate final result (ADC\_Rn).

Address: Base address + 54h offset

#### ADCx\_OFs field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 SIGN	Sign bit 0 The offset value is added with the raw result 1 The offset value is subtracted from the raw converted value
OFS	Offset value User configurable offset value.

### 66.8.11 Calibration value register (ADCx\_CAL)

Contains calibration information that is generated by the calibration function. This register contains a calibration value of four bits(CAL[3:0]); this is automatically set after the self calibration sequence is done (ADC\_SC[CAL] bit is cleared). If this register is written to by the user after calibration, the linearity error specifications may not be met.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 67.2 Overview

The ADC External Trigger Control (ADC\_ETC) module enables multiple trigger sources to share the ADC modules in a TIME-Division-Multiplexing (TDM) way. The external triggers can be from the Cross BAR (XBAR) and TSC (Touch Screen Controller) in SOC. The ADC\_ETC has one TSC external trigger and 8 external triggers input from XBAR. The TSC external trigger is shared by TSC0 and TSC1. The TRIG0-TRIG3 input from XBAR together with TSC0 belong to channel0, while TRIG4-TRIG7 together with TSC1 belong to channel1. Channel0 controls ADC1 and Channel1 controls ADC2. When CTRL[TSC\_BYPASS] is set, TSC external trigger will control ADC2 directly. The ADC\_ETC also supports SyncMode. When TRIGa\_CTRL[SYNC\_MODE] is set, the

ADC\_ETC trigger source will control ADC1 and ADC2 synchronously. The SyncMode can not be used when TSC\_BYPASS is active. The ADC\_ETC can support interrupt mode and DMA mode (controlled independently).

### NOTE

The trigger in this chapter refers the trigger of ADC\_ETC, except when referring to the ADC trigger explicitly.

## 67.2.1 Block diagram

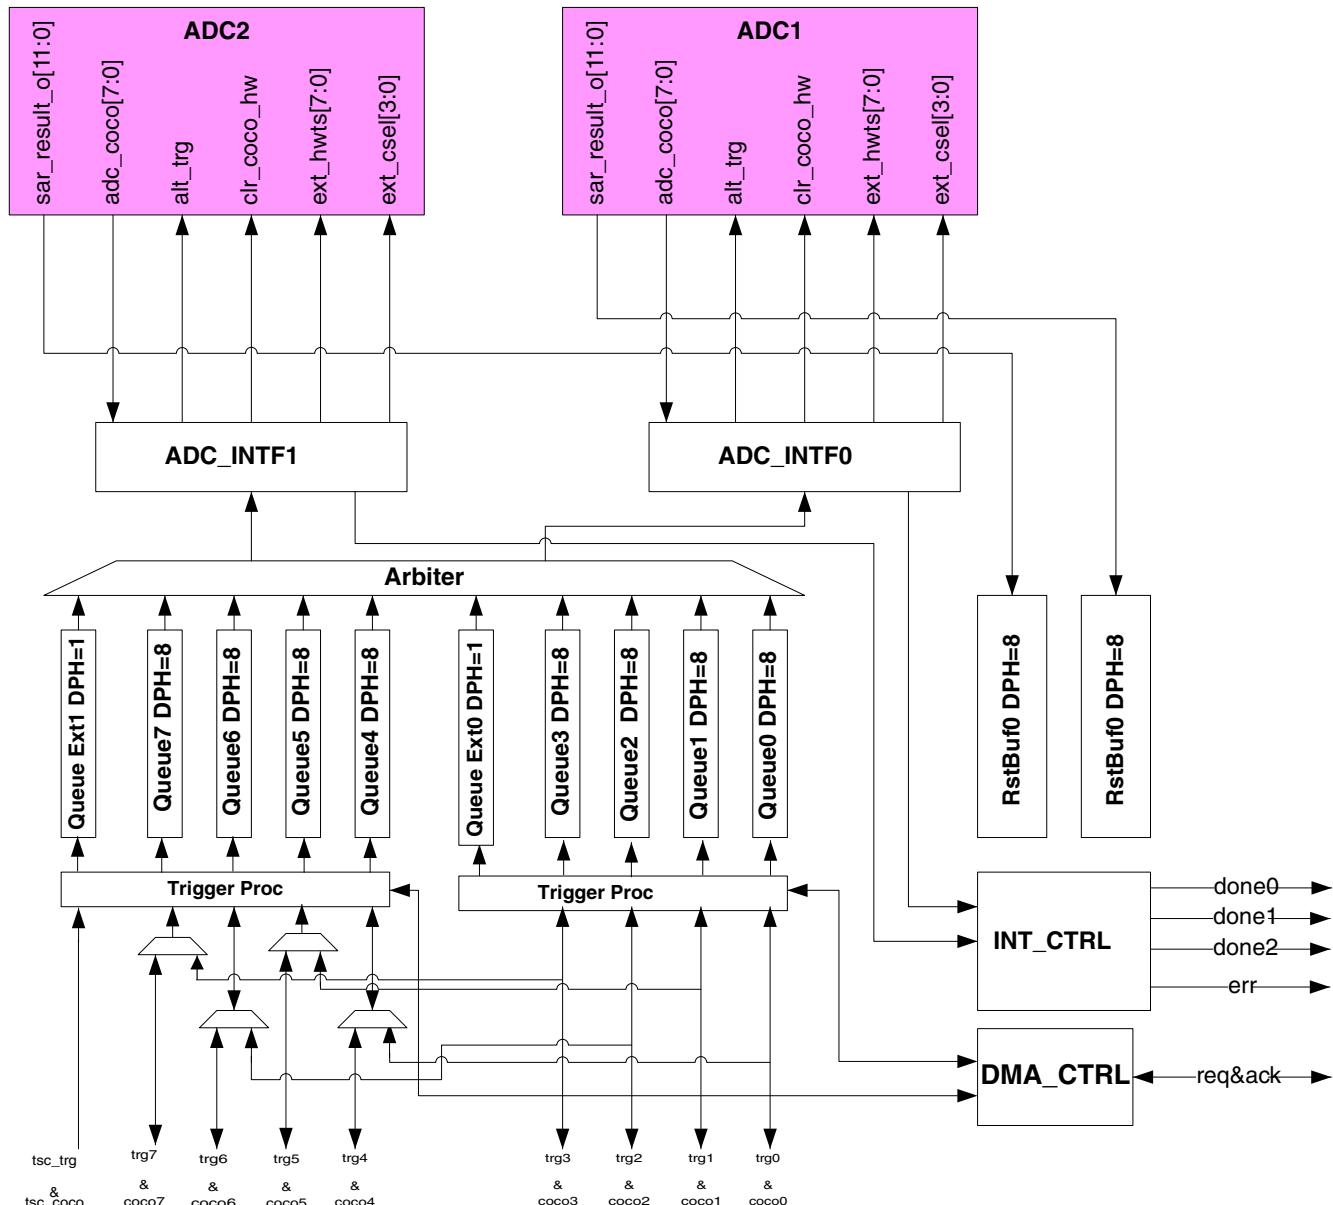

Figure 67-1. ADC\_ETC block diagram

## 67.2.2 Features

The ADC\_ETC includes the following features:

- External Trigger Interface
  - ADC control interface is connected with 2 ADCs, and support up to 8 Hardware External Trigger (ext\_hwts[7:0] in ADC\_ETC block diagram) for each ADC
- Capable of triggering dual ADCs in SyncMode or AsyncMode:
  - In SyncMode ADC1 and ADC2 are controlled by the same trigger source of ADC\_ETC.
  - In AsyncMode ADC1 and ADC2 are controlled by separate trigger source of ADC\_ETC.
- Support up to 8 external trigger inputs, input from XBAR (4 for each ADC, TRIG0-TRIG3 for ADC1, and TRIG4-TRIG7 for ADC2).
  - One external trigger of ADC\_ETC can launch up to 8 sequential triggers to ADC, which are called a trigger chain, and each trigger is called a segment of the trigger chain.
  - Flexible ADC trigger interval and initial delay control.
  - Each trigger of ADC\_ETC can be configured as HW or SW trigger mode.
- ADC result holding and status reporting
- ADC\_ETC trigger auto hold and arbitration
  - Each trigger of ADC\_ETC can be configured with a fixed priority. External trigger with the highest priority is served first.
  - Hold one trigger event upon when it failed to win the arbitration or ADC is busy.
- Supports ADC trigger interface cascading
- Supports interrupt mode. When interrupt mode is selected and one ADC conversion is done, an interrupt request signal will be generated on one of the Done0~Done2 interrupt outputs.
- Supports DMA mode. When DMA is enabled and one ADC conversion is done, a DMA request will be sent. 2 trigger modes of DMA can be selected by configuring CTRL[DMA\_MODE\_SEL].

## 67.3 Functional description

The ADC\_ETC block works with XBAR and TSC blocks to share with the ADC modules. The following sections describe functional details of the ADC\_ETC module.

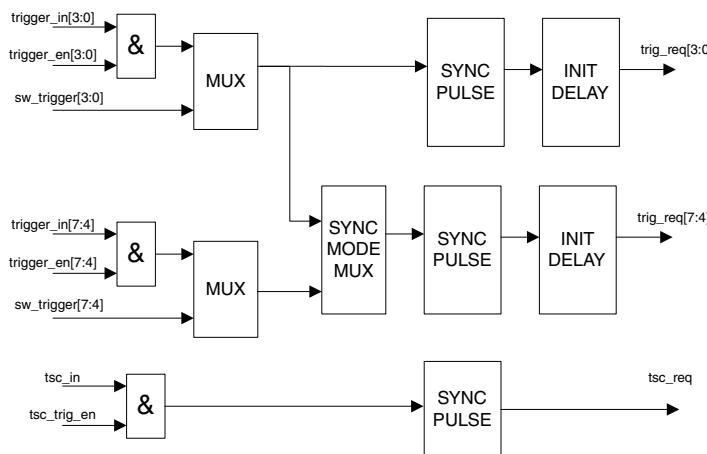

### 67.3.1 Operations

This section describes the ADC\_ETC module's operations.

The trigger process is used to handle the multiple trigger sources based on the settings in registers. CTRL[TRIG\_ENABLE] can be used to mask the input hardware trigger sources. TRIGa\_CTRL[TRIG\_MODE] selects the hardware trigger source or software trigger source for TRIGa of ADC\_ETC. The selected trigger source is double synchronized to a synchronous positive pulse and the pulse will be sent to the arbiter after initial delay defined by TRIGa\_COUNTER[INIT\_DELAY].

If TRIGa\_CTRL[SYNC\_MODE] is set, the trigger process will control TRIGa and TRIG(a+4) synchronously. In this mode, the initial delay of TRIGa and TRIG(a+4) is controlled by the settings of TRIGa, while other settings are independent.

The trigger process diagram is indicated as below:

**Figure 67-2. Trigger process diagram**

As showing in ADC\_ETC block diagram, the trig\_req[7:0] output from trigger process will go to the arbiter with a queue module.

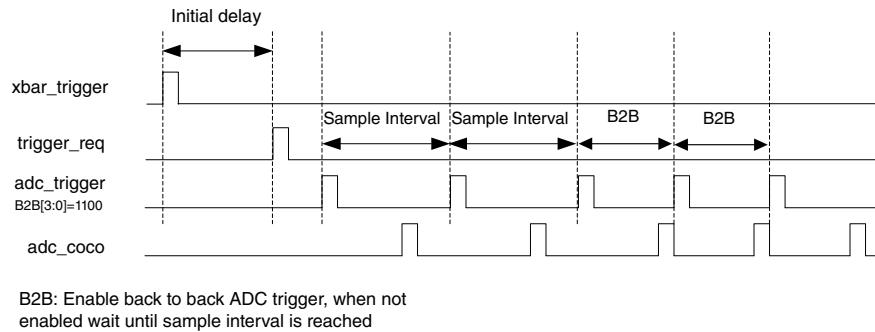

The arbiter trigger will approve the request from XBAR and TSC which has the highest priority defined in TRIGa\_CTRL[TRIG\_PRIORITY]. There are total of eight priority levels available for each trigger request, where 7 is the highest priority level and 0 is the lowest priority level. If multiple trigger requests have the same priority level, then the round-robin mechanism will be applied, and the trigger with larger number owns the higher priority. The trigger request is granted only when the previous trigger has finished and the ADC module is IDLE. When in SYNC mode, the trigger request is granted only when both ADC modules are IDLE state.

When there is a trigger request that is granted, the ADC\_ETC sends several triggers of ADC as a chain of trigger, with ext\_hwts[7:0] as ADC trigger selection signal, and with tcmd[3:0] defining the TCMD to ADC. When the ADC conversion done, the ADC sends back adc\_coco to the ADC\_ETC, which has the same width as ext\_hwts and indicates which trigger the current sar\_result\_o is for, then the ADC\_ETC stores the ADC converted results into the internal registers .

At the same time, interrupt asserts according to the software configuration. After that, the next trigger is sent after a interval delay configured by TRIGa\_COUNTER[SAMPLE\_INTERVAL], until all triggers in the chain are processed. When complete the the last trigger in chain, ADC\_ETC sends the coco signal to mark the end of one of ADC\_ETC external trigger, and a DMA request will be generated if DMA\_CTRL[TIRGa\_ENABLE] is set to 1.

Each ADC trigger in the trigger chains, initiated by trigger requests of ADC\_ETC, has separate configurations by software. These configurations include Interrupt selection (IE), Back to Back ADC trigger (B2B), HWTS and CSEL to ADC. The ADC\_ETC have interrupt outputs of Done0, Done1, Done2 and Error Interrupt. The Done0/1/2 interrupts are controlled by software for each ADC trigger. IEEx selects which port the interrupt occurs on. (IEEx=2'b00 means no interrupt, while 2'b01~2'b11 mean selecting Done0~Done2 correspondingly). Error interrupt occurs when there is an external trigger ignored by ADC\_ETC due to the previous trigger not finished yet.

The ETC-ADC interface timing is indicated in below diagrams:

**Figure 67-3. ETC-ADC interface timing**

After one ADC conversion, the next trigger in the chain starts as soon as possible if B2B is enabled. Otherwise the next trigger does not start until waiting until interval delay is reached.

As shown in ETC-ADC interface timing, due to B2B[3:0]=1100, the slots after the first and second adc\_trigger are equal to interval delay, but the slots after the third and fourth adc\_trigger are shorter.

The length of initial delay and interval delay are configurable, the formulas to calculate initial delay and interval delay are described in the description of the TRIGa\_COUNTER.

### 67.3.2 Clocks

The ADC\_ETC module has one global functional clock: ipg\_clk. The ipg\_clk is used for register read/write operations, also all the functionality inside the ADC\_ETC module are synchronized to this clock.

The XBAR and TSC input may be synchronous or asynchronous with the ADC\_ETC clock.

### 67.3.3 Reset

The ADC\_ETC has two resets: ipg\_hard\_async\_reset\_b and sw\_reset\_n. The ipg\_hard\_async\_reset\_b is a hardware reset, which resets all registers in ADC\_ETC block. The sw\_reset\_n is a software reset, which can reset all registers except itself by software.

**NOTE**

`sw_reset_n` is generated by writing logic 1 into `CRTL[SOFTRST]`, while `ipg_hard_async_reset_b` is generated by SoC hardware.

## 67.4 Initialization

Before using the ADC\_ETC module, the following initialization procedure must be performed:

1. Configure the Global Control bits, include selecting DMA mode, enabling triggers which will be used, and setting pre-division factor.
2. Set DMA enable bits as needed.
3. Configure control bits for each enabled trigger, include enabling or disabling synchronization mode, assigning trigger priority, setting the length of trigger chain, selecting trigger mode and setting the initial and interval delay of this trigger.
4. According to the length of trigger chain, several segments of the chain should be configured. The configurations of each segment contain:
  - a. setting the DONE interrupt for this chain, enabling or disabling B2B mode;
  - b. selecting which trigger of ADC will be triggered, setting the ADC command.

After the initialization of ADC\_ETC, the initialization of the ADC module should also be confirmed before launching a trigger to ADC\_ETC.

## 67.5 Application information

This section describes applications supported by the ADC\_ETC module.

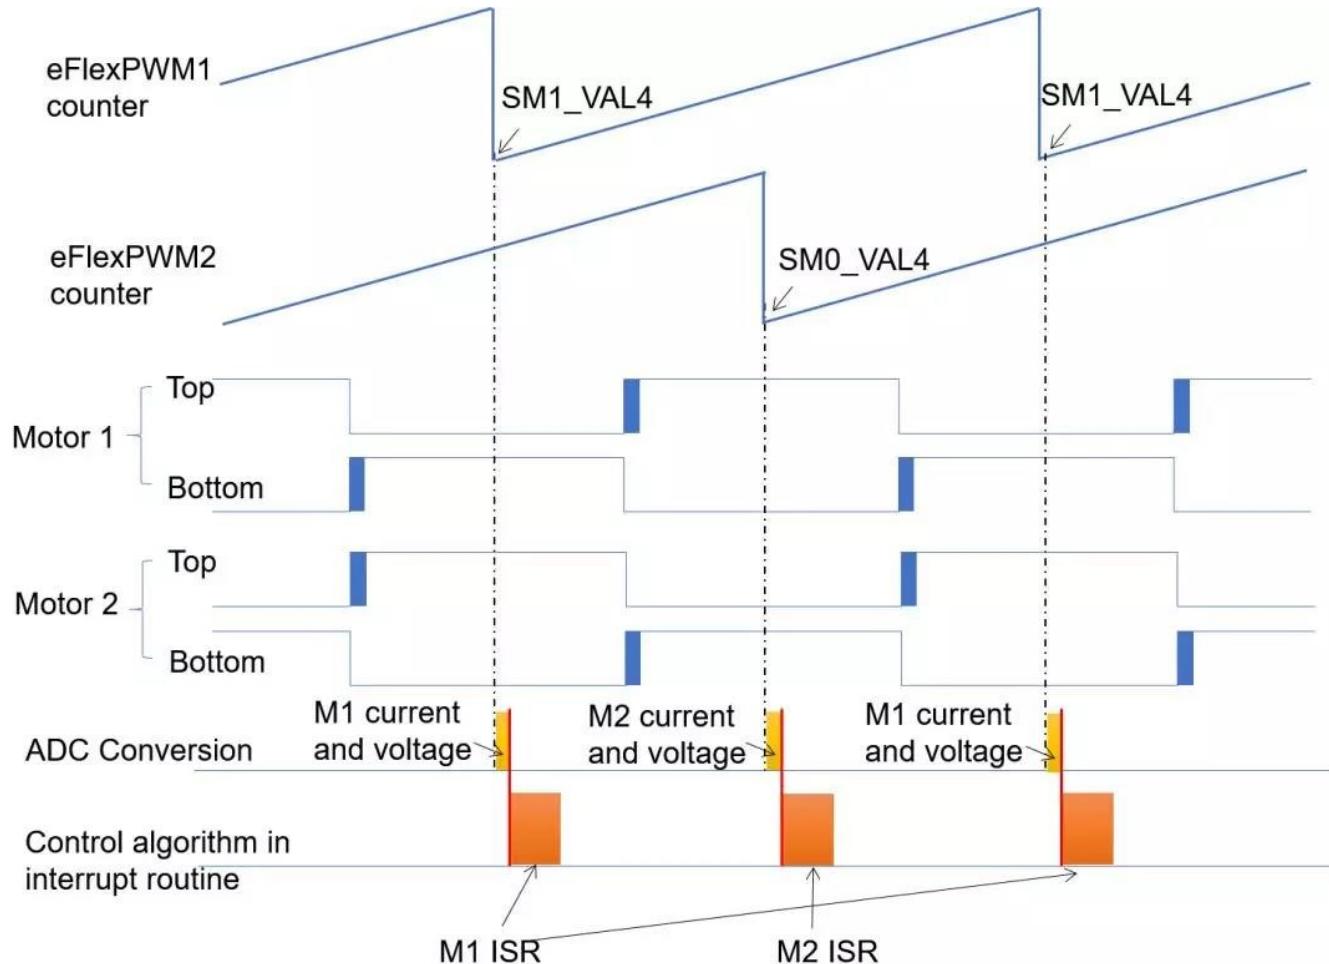

### 67.5.1 ADC Trigger Concept – Dual PMSM motor control

ADC\_ETC's flexible configuration is suitable for complex application timing design. The following describes the configuration scheme of ADC\_ETC for dual motor control. There is a 180-degrees phase lag between the PWMs of dual motors, and on this basis ADC\_ETC uses the triggers from eFlexPWM to implement time division sampling of analog signals of dual motors.

The figure below presents the synchronization between ADC and PWMs.

## Application information

Once eFlexPWM1 counter reaches submodule 1 VAL4, ADC\_ETC will be triggered to control ADCs to sampling analog signal of motor 1. After ADC conversation done, ADC\_ETC\_DONE0 interrupt is enabled to run motor 1 control algorithm. Once eFlexPWM2 counter reaches submodule 0 VAL4, ADC\_ETC will be triggered to control ADCs to sampling analog signal of motor 2. After ADC conversation done, ADC\_ETC\_DONE1 interrupt is enabled to run motor 2 control algorithm.

**Figure 67-4. Synchronization between ADC and PWMs**

The external triggers are generated from the Cross BAR (XBAR) or other sources. The ADC scan is started via ADC\_ETC. The following is the key configuration point for this application.

- Enable external XBAR trigger 0 and 1, both ADCs have their own trigger segments.
- The trigger chain length is set to 2. The back-to-back ADC trigger mode is enabled.

- Enable the Sync Mode. In the Sync Mode, ADC1 and ADC2 are controlled by the same trigger source.
- Both trigger chain has their own finished interrupt. When Chain 4 triggered by TRIG0 is finished, enable DONE0 interrupt. When Chain 5 triggered by TRIG1 is finished, enable DONE1 interrupt.

The figure below shows configuration of ADC\_ETC to control dual ADCs in this dual motor application.

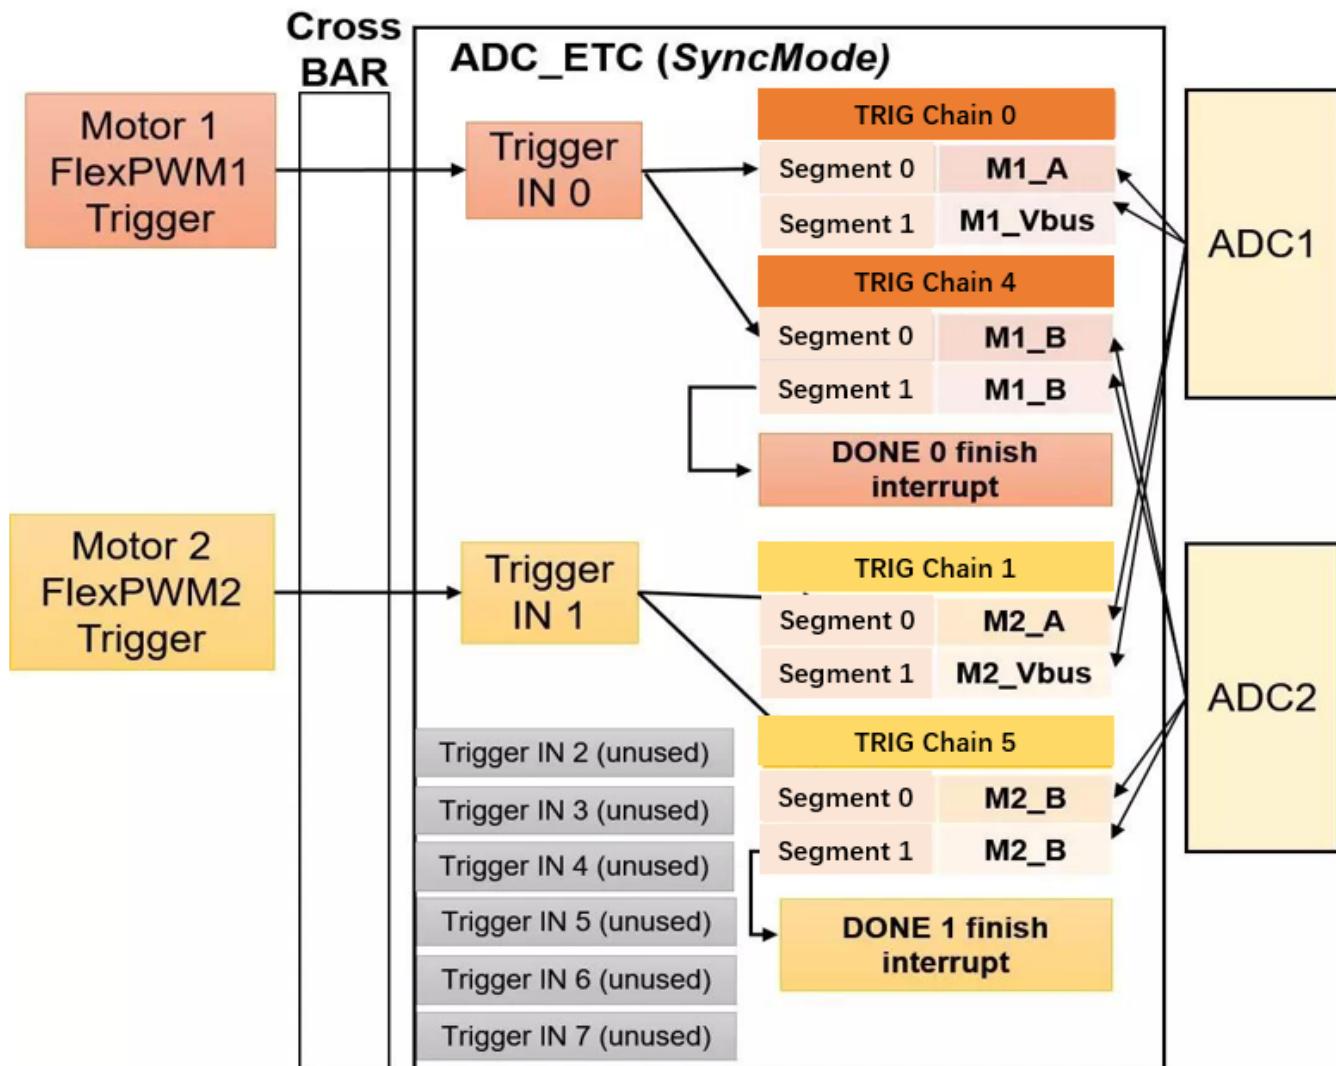

Figure 67-5. The configuration of ADC\_ETC for dual motor control

## 67.6 Memory Map and register definition

This section includes the ADC\_ETC module memory map and detailed descriptions of all registers.

### 67.6.1 ADC\_ETC register descriptions

The descriptions below will list the memory map and give detailed explanations for all registers and the bit fields of the registers.

#### 67.6.1.1 ADC\_ETC memory map

ADC\_ETC base address: 403B\_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	ADC_ETC Global Control Register (CTRL)	32	RW	C000_0000h
4h	ETC DONE0 and DONE1 IRQ State Register (DONE0_1_IRQ)	32	W1C	0000_0000h

### 67.6.1.2 ADC\_ETC Global Control Register (CTRL)

#### 67.6.1.2.1 Offset

Register	Offset
CTRL	0h

### 67.6.1.2.2 Function

This register controls various global functions of the ADC\_ETC, such as enabling the external XBAR triggers, setting the pre-division factor for trigger delay and interval, and selecting the trigger type of the DMA\_REQ. In addition, this register contains SOFTRST to reset all registers inside ADC\_ETC.

### 67.6.1.2.3 Diagram

### 67.6.1.2.4 Fields

Field	Function
31 SOFTRST	Software synchronous reset, active high. 0b - ADC_ETC works normally. 1b - All registers inside ADC_ETC will be reset to the default value.
30 TSC_BYPASS	TSC Bypass <b>NOTE:</b> To use ADC2, this bit should be cleared. 0b - TSC not bypassed. 1b - TSC is bypassed to ADC2, that means TSC will control ADC2 directly.
29 DMA_MODE_SEL	Select the trigger type of the DMA_REQ. 0b - Trig DMA_REQ with latched signal, REQ will be cleared when ACK and source request cleared. 1b - Trig DMA_REQ with pulsed signal, REQ will be cleared by ACK only.
28-24	Reserved

Table continues on the next page...

## Memory Map and register definition

Field	Function
—	
23-16 PRE_DIVIDER	Pre-divider for trig delay and interval. The meaning of this field will be explained in the description of TRIGa_COUNTER.
15-13 EXT1_TRIG_PR ORITY	External TSC1 trigger priority, 7 is highest priority, while 0 is lowest.
12 EXT1_TRIG_EN ABLE	TSC1 TRIG enable register. 0b - disable external TSC1 trigger. 1b - enable external TSC1 trigger.
11-9 EXT0_TRIG_PR ORITY	External TSC0 trigger priority, 7 is highest priority, while 0 is lowest.
8 EXT0_TRIG_EN ABLE	TSC0 TRIG enable register. 0b - disable external TSC0 trigger. 1b - enable external TSC0 trigger.
7-0 TRIG_ENABLE	TRIG enable register. 0000000b - disable all 8 external XBAR triggers. 00000001b - enable external XBAR trigger0. 00000010b - enable external XBAR trigger1. 00000011b - enable external XBAR trigger0 and trigger1. 1111111b - enable all 8 external XBAR triggers.

## 67.6.1.3 ETC DONE0 and DONE1 IRQ State Register (DONE0\_1\_IRQ)

### 67.6.1.3.1 Offset

Register	Offset
DONE0_1_IRQ	4h

### 67.6.1.3.2 Function

This register has the state for ETC DONE0 and DONE1 interrupts.

#### NOTE

The IRQs can be cleared by writing 1 to the corresponding bits.

## 67.6.1.5 ETC DMA control Register (DMA\_CTRL)

### 67.6.1.5.1 Offset

Register	Offset
DMA_CTRL	Ch

### 67.6.1.5.2 Function

This register has the control and status bit for the DMA of ADC\_ETC. Each trigger has separate enabling and status bit in this register. The control bit enables the DMA request for each trigger, and the status bit indicates whether the corresponding trigger request was detected.

#### NOTE

TRIGa\_REQ can be cleared by writing 1 to the corresponding bit.

### 67.6.1.5.3 Diagram

### 67.6.1.5.4 Fields

Field	Function
31-24 —	Reserved
23 TRIG7_REQ	Flag bit for DMA request. TRIG7_REQ being active indicates trigger7 done and a DMA transmission is needed. If TRIG7_ENABLE is also set, a DMA request will be sent. 0b - TRIG7_REQ not detected. 1b - TRIG7_REQ detected.
22 TRIG6_REQ	Flag bit for DMA request. TRIG6_REQ being active indicates trigger6 done and a DMA transmission is needed. If TRIG6_ENABLE is also set, a DMA request will be sent. 0b - TRIG6_REQ not detected. 1b - TRIG6_REQ detected.
21 TRIG5_REQ	Flag bit for DMA request. TRIG5_REQ being active indicates trigger5 done and a DMA transmission is needed. If TRIG5_ENABLE is also set, a DMA request will be sent. 0b - TRIG5_REQ not detected. 1b - TRIG5_REQ detected.
20 TRIG4_REQ	Flag bit for DMA request. TRIG4_REQ being active indicates trigger4 done and a DMA transmission is needed. If TRIG4_ENABLE is also set, a DMA request will be sent. 0b - TRIG4_REQ not detected. 1b - TRIG4_REQ detected.
19 TRIG3_REQ	Flag bit for DMA request. TRIG3_REQ being active indicates trigger3 done and a DMA transmission is needed. If TRIG3_ENABLE is also set, a DMA request will be sent. 0b - TRIG3_REQ not detected. 1b - TRIG3_REQ detected.
18 TRIG2_REQ	Flag bit for DMA request. TRIG2_REQ being active indicates trigger2 done and a DMA transmission is needed. If TRIG2_ENABLE is also set, a DMA request will be sent. 0b - TRIG2_REQ not detected. 1b - TRIG2_REQ detected.
17 TRIG1_REQ	Flag bit for DMA request. TRIG1_REQ being active indicates trigger1 done and a DMA transmission is needed. If TRIG1_ENABLE is also set, a DMA request will be sent. 0b - TRIG1_REQ not detected. 1b - TRIG1_REQ detected.
16 TRIG0_REQ	Flag bit for DMA request. TRIG0_REQ being active indicates trigger0 done and a DMA transmission is needed. If TRIG0_ENABLE is also set, a DMA request will be sent. 0b - TRIG0_REQ not detected. 1b - TRIG0_REQ detected.
15-8 —	Reserved
7 TRIG7_ENABLE	Enable DMA request when TRIG7 done. 0b - TRIG7 DMA request disabled. 1b - TRIG7 DMA request enabled.
6 TRIG6_ENABLE	Enable DMA request when TRIG6 done. 0b - TRIG6 DMA request disabled. 1b - TRIG6 DMA request enabled.

Table continues on the next page...

Field	Function
5 TRIG5_ENABLE	Enable DMA request when TRIG5 done. 0b - TRIG5 DMA request disabled. 1b - TRIG5 DMA request enabled.
4 TRIG4_ENABLE	Enable DMA request when TRIG4 done. 0b - TRIG4 DMA request disabled. 1b - TRIG4 DMA request enabled.
3 TRIG3_ENABLE	Enable DMA request when TRIG3 done. 0b - TRIG3 DMA request disabled. 1b - TRIG3 DMA request enabled.
2 TRIG2_ENABLE	Enable DMA request when TRIG2 done. 0b - TRIG2 DMA request disabled. 1b - TRIG2 DMA request enabled.
1 TRIG1_ENABLE	Enable DMA request when TRIG1 done. 0b - TRIG1 DMA request disabled. 1b - TRIG1 DMA request enabled.
0 TRIG0_ENABLE	Enable DMA request when TRIG0 done. 0b - TRIG0 DMA request disabled. 1b - TRIG0 DMA request enabled.

## 67.6.1.6 ETC\_TRIGGER Control Register (TRIG0\_CTRL - TRIG7\_CTRL)

### 67.6.1.6.1 Offset

For  $a = 0$  to 7:

Register	Offset
TRIGa_CTRL	10h + ( $a \times 28h$ )

### 67.6.1.6.2 Function

This register contains the control bits for trigger, such as selecting synchronization mode, setting trigger priority and setting the length of trigger chain. It also contains a bit for selecting trigger mode between hardware trigger and software trigger, and a self-clearing bit for launching a software trigger.

### 67.6.1.6.3 Diagram

### 67.6.1.6.4 Fields

Field	Function
31-24 —	Reserved
23-17 —	Reserved
16 SYNC_MODE	Trigger synchronization mode selection. <b>NOTE:</b> Setting SYNC_MODE = 1 for TRIGa or TRIG(a+4) represents the same meaning. 0b - Synchronization mode disabled, TRIGa and TRIG(a+4) are triggered independently. 1b - Synchronization mode enabled, TRIGa and TRIG(a+4) are triggered by TRIGa source synchronously.
15 —	Reserved
14-12 TRIG_PRIORITY	External trigger priority, 7 is highest priority, while 0 is lowest. <b>NOTE:</b> When more than one triggers use the same level setting of priority, then round-robin mechanism implemented and the trigger with larger number owns the higher priority.
11 —	Reserved
10-8 TRIG_CHAIN	The number of segments inside the trigger chain of TRIGa. 000b - Trigger chain length is 1 001b - Trigger chain length is 2 010b - Trigger chain length is 3 011b - Trigger chain length is 4 100b - Trigger chain length is 5 101b - Trigger chain length is 6

Table continues on the next page...

Field	Function
	110b - Trigger chain length is 7 111b - Trigger chain length is 8
7-5 —	Reserved
4 TRIG_MODE	Trigger mode selection. 0b - Hardware trigger. The software trigger will be ignored. 1b - Software trigger. The hardware trigger will be ignored.
3-1 —	Reserved
0 SW_TRIG	Software trigger. <b>NOTE:</b> This field is self-clearing. 0b - No software trigger event generated. 1b - Software trigger event generated.

## 67.6.1.7 ETC\_TRIG Counter Register (TRIG0\_COUNTER - TRIG7\_COUNTER)

### 67.6.1.7.1 Offset

For  $a = 0$  to 7:

Register	Offset
TRIGa_COUNTER	14h + ( $a \times 28h$ )

### 67.6.1.7.2 Function

This register controls the initial delay ahead the first ADC trigger and interval delay between ADC triggers launched by the same ADC\_ETC trigger.

### 67.6.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 67.6.1.7.4 Fields

Field	Function
31-16 SAMPLE_INTE RVAL	TRIGGER sampling interval counter. When B2B is unset: $\text{Interval\_delay} = (\text{SAMPLE\_INTERVAL}+1) * (\text{PRE\_DIVIDER}+1) * \text{ipg\_clk}$
15-0 INIT_DELAY	TRIGGER initial delay counter. $\text{Initial\_delay} = (\text{INIT\_DELAY}+1) * (\text{PRE\_DIVIDER}+1) * \text{ipg\_clk}$

## 67.6.1.8 ETC\_TRIG Chain 0/1 Register (TRIG0\_CHAIN\_1\_0 - TRIG7\_CHAIN\_1\_0)

### 67.6.1.8.1 Offset

For  $a = 0$  to 7:

Register	Offset
TRIGa_CHAIN_1_0	18h + ( $a \times 28h$ )

### 67.6.1.8.2 Function

This register controls ETC\_TRIG segment 0/1 configuration, such as enabling and selecting interrupt, setting back-to-back mode, selecting ADC trigger and trigger command.

### 67.6.1.8.3 Diagram

### 68.2 Overview

This block describes the Touch Screen Controller (TSC), which is used for ADC and touch screen analogue block.

TSC is responsible for providing control of ADC and touch screen analogue block to form a touch screen system, which achieves function of touch detection and touch location detection. The controller utilizes ADC hardware trigger function and control switches in touch screen analogue block. The controller only supports 4-wire of 5-wire screen touch modes.

Figure 68-1. TSC block diagram

### 68.2.1 Features

The features of TSC controller are following.

- Configure registers: 32-bit, fully support sky-blue bus interface
- 4-wire or 5-wire mode of touch screen
- Low power wake up functions
- ADC average function and custom 8-bit, 10-bit, and 12-bit conversion result
- Custom pre-charge and de-glitch threshold time setting
- Total control five analogue groups of switches
- Fully asynchronous interface to ADC and analogue switches
- Easy software operation
- Software takes control of operation flow
- Strong debug functions—enable software recognize the IP as a transparent box and operation output directly
- Software reset function

## 68.3 Functional Description

This block works with ADC and TSC analogue to form a touch screen system. The system is responsible to detect touch on screen and measure the coordinate of the touch point. The touch screen controller, which is at the heart of the system, given control to TSC analogue and ADC. TSC analogue provides positive or negative voltage to the screen if the touch screen controller provides relevant signals. The ADC convert coordinates value if requested by touch screen controller.

### 68.3.1 Operating modes

The TSC can be worked in the following modes.

#### 68.3.1.1 Idle

The TSC always stays at idle status if finish a coordinate measurement. The TSC only starts to detect a touch or starts to measure coordinate value if set the start\_sen bit. The TSC returns to idle status after finish current task if disable bit is set by software.

#### 68.3.1.2 Pre-charge

Pre-charge is a preparation for detection stage. Before detection stage, the upper layer of screen is required to charge to positive high. The time required for the pre-charge can be set in the pre-charge\_timer.

#### 68.3.1.3 Detection

Detection is a stage to sense touch detect on the screen. This stage is initiated a delay (set by pre-charge\_timer) in order to wait enough time for the lower screen layer to achieve even-potential status. After the TSC send out detect enable signal to detect signal from analogue, after receiving the signal, TSC starts to measure coordinates or waiting for the instruction from software according to the value of auto\_measure. If auto\_measure is set then the TSC automatically measures coordinates after detect a touch. Otherwise TSC

waits for software order after detects a touch (and generates an interrupt). The software can choose to drop the measure (and return back to idle) by setting drop\_measure, or start the measure by setting start\_measure.

### **68.3.1.4 Measurement**

During the measure stage, the TSC hardware gives control to TSC analogue and ADC. No software operation is needed. If requesting average function, do average configuration for ADC.

### **68.3.1.5 Data valid check**

After measure the coordinate value, TSC do a touch detects again. If no touch has been detected, then previous measured coordinates' value is invalid. Otherwise, the measured coordinates' value is valid.

### **68.3.1.6 Interrupt**

Each interrupt provides three software interface bits: interrupt enable, interrupt signal enable, and interrupt signal.

### **68.3.1.7 Reset**

The TSC has two resets: ipg\_reset\_b and sw\_rst. The ipg\_reset\_b reset is a hardware reset, which resets all registers in TSC block. While the sw\_rst is a software reset, which resets every register except ips directly access ones.

### **68.3.1.8 Debug mode**

The TSC provides fully software control signals. After debug\_en has been set, then all TSC outputs will be controlled by software. Software can also observe all TSC inputs through debug interface. Furthermore, the debug registers also provides current state machine states. Software can always check the current hardware state.

## 68.3.2 Configuration

### 68.3.2.1 TSC configurations

The following tables provide 4-wire and 5-wire screen touch modes.

**Table 68-2. 4-wire screen touch mode**

	wiper	ynlr	ypll	xnur	xpul
X measurement	OFF	OFF	OFF	LOW	HIGH
Y measurement	OFF	LOW	HIGH	OFF	OFF
Pre-charge	OFF	OFF	OFF	HIGH (200K, PULL UP)	HIGH (200K, PULL UP)
Intermediate	OFF	OFF	OFF	OFF	HIGH (200K)
Touch screen detection	OFF	LOW	LOW	OFF	HIGH (200K)

**Table 68-3. 5-wire screen touch mode**

	wiper	ynlr	ypll	xnur	xpul
X measurement	OFF	LOW	HIGH	LOW	HIGH
Y measurement	OFF	LOW	LOW	HIGH	HIGH
Pre-charge	HIGH (200K, PULL UP)	OFF	OFF	OFF	OFF
Intermediate <sup>1</sup>	HIGH (200K)	OFF	OFF	OFF	OFF
Touch screen detection	HIGH (200K)	LOW	LOW	OFF	OFF

1. All other intermediate states switch to OFF.

### 68.3.2.2 TSC-ADC-TSC analogue configuration

The touch screen controller needs to co-work with ADC and TSC analogue.

The ADC is responsible for analogue value conversion. Following tables show the channels that the ADC used.

**Table 68-4. 4-wire screen touch mode**

X measurement	Channel 1	Connects to TSC ana YNLR
---------------	-----------	--------------------------

*Table continues on the next page...*

**Table 68-4. 4-wire screen touch mode (continued)**

Y measurement	Channel 3	Connects to TSC ana XNUR
---------------	-----------	--------------------------

**Table 68-5. 5-wire screen touch mode**

X measurement	Channel 0	Connects to TSC ana WIPER
Y measurement	Channel 0	Connects to TSC ana WIPER

### 68.3.2.3 TSC, TSC analogue and ADC connection

The following table describes the connections among the TSC, TSC analogue, and ADC.

**Table 68-6. TSC, TSC analogue and ADC connection**

TSC controller ports	TSC analogue IP ports	TSC analogue system integration instance Name	ADC Ain ports
wiper_pull_up	pu_en	1	Ain [0]
wiper-200k_pull_up	pull_up-200k_en		
wiper_pull_down	pd_en		
ynlr_pull_up	pu_en	2	Ain [1]
ynlr_200k_pull_up	pull_up_200k_en		
ynlr_pull_down	pd_en		
ypll_pull_up	pu_en	3	Ain [2]
ypll_200k_pull_up	pull_up_200k_en		
ypll_pull_down	pd_en		
xnur_pull_up	pu_en	4	Ain [3]
xnur_200k_pull_up	pull_up_200k_en		
xnur_pull_down	pd_en		
xpul_pull_up	pu_en	5	Ain [4]
xpul_200k_pull_up	pull_up_200k_en		
xpul_pull_down	pd_en		

### 68.3.2.4 TSC and GPIO

From TSC point of view, it does not care what kinds of PAD used. It can use digital pad or analogue pad.

**Table 68-7. The ports used in TSC and GPIO**

TSC function ports	TSC analogue instance	ADC Ain pin	GPIO ports
wiper	1	Ain [0]	GPIO_AD_B1_11 pin 21
ynlr	2	Ain [1]	GPIO_AD_B1_12 pin 38 (T4.1)
yll	3	Ain [2]	GPIO_AD_B1_13 pin 39 (T4.1)
xnur	4	Ain [3]	GPIO_AD_B1_14 pin 26
xpul	5	Ain [4]	GPIO_AD_B1_15 pin 27

**NOTE**

For the PAD used for TSC, make sure the PAD behavior , such as a wire only connects to the Pin and TSC analogue switches.

For the PAD used for GPIO, for example, has a keeper to prevent the GPIO pad working from a wire only connects the Pin and TSC. In such condition, disable keeper when TSC working.

### 68.3.2.5 ADC-TSC co-working

The TSC is designed to work with the ADC. Two IP must work together to achieve the correct functions. The coordinate work includes two steps:

1. TSC starts ADC

TSC sends two signals: trigger and hardware trigger select signal: HWTS[4:0].

ADC regards triggers as clock to capture the select signal: HWTS. The details of information about trigger and HWTS is show in the ADC hardware trigger chapter. The TSC hardware makes sure that the HWTS signals ready one clock cycles before sending trigger signals. Make sure that the trigger delay is less than HWTS delay + one clock cycle.

The TSC send HWTS as in the following table:

	TSC 4-wire mode	TSC 5-wire mode
x-coordinate measure	HWTS = 5'b01000	HWTS = 5'b10000
y-coordinate measure	HWTS = 5'b00010	HWTS = 5'b10000

TSC HWTS[4:0] connects to the ADC HWTS[4:0]. The integration change will lead change in driver implementation. On ADC side, HWTS = 1 << x indicates the x logic channel is selected to start hardware ADC conversion. Configure ADC\_HC<sub>x</sub> to configure x logic channel and conversion will store in ADC\_Rx.

Each ADC hardware trigger logic channel can be configured to one of many physical channels. The details of the ADC configuration, refer to the ADC hardware trigger chapter. Software driver configures the physical ADC. A sample configuration is shown in the following table.

	<b>TSC 4-wire mode</b>	<b>TSC 5-wire mode</b>
x-coordinate measure	ADC measures channel 1 or 2, so configure ADC_HC3[ADCH] to 1 or 2.	ADC measure channel 0, so configure ADC_HC[4] to 0.
y-coordinate measure	ADC measures channel 3 or 4, so configure ADC_HC1[ADCH] to 3 or 4.	ADC measures channel 0, so configure ADC_HC[4] to 0.

Before TSC starts work, software driver configure ADC\_HC<sub>x</sub>. TSC hardware automatically sends trigger and HWTS at the correct time.

## 2. ADC sends back converted value and complete signals to TSC.

When ADC finishes conversion, the ADC would send a complete signal to TSC. A set of handshake signals between ADC and TSC makes sure that the TSC could receive complete signals, store correct ADC converted value, and clear ADC coco signals at correct order. All parts of this step are automatically done by hardware.

### NOTE

For different ADC conversion modes, such 8-bit, 10-bit, 12-bit mode, average mode, please configure in ADC registers.

## 68.4 TSC Memory Map/Register Definition

The TSC Memory Map and Register Definition is described in the following section.

**TSC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

## TSC FLOW CONTROL field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 DISABLE	<p>This bit is for SW disable registers. After set this bit, the hardware returns to idle status after finish the current state operation. SW must check the SW_IDLE bit to confirm that the controller has return to idle status. It's a HW self-clean bit.</p> <p>0 Leave HW state machine control 1 SW set to idle status</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 START_SENSE	<p>Start Sense</p> <p>It's a HW self-clean bit.</p> <p>0 Stay at idle status 1 Start sense detection and (if auto_measure set to 1) measure after detect a touch</p>
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 DROP_MEASURE	<p>Drop Measure</p> <p>This field indicates whether start measure X/Y coordinate value after detect a touch It's a HW self-clean bit.</p> <p>0 Do not drop measure for now 1 Drop the measure and controller return to idle status</p>
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 START_MEASURE	<p>Start Measure</p> <p>This field indicates whether start measure X/Y coordinate value after detect a touch It's a self-clean bit.</p> <p>0 Do not start measure for now 1 Start measure the X/Y coordinate value</p>
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 SW_RST	<p>Soft Reset</p> <p>This is a synchronization reset, which reset all HW registers.</p> <p><b>NOTE:</b> All SW accessible registers would keep as it original setting Software reset would be self-clear.</p>

#### 68.4.4 Measure Value (TSC MEASURE VALUE)

Address: 400E 0000h base + 30h offset = 400E 0030h

**TSC\_MEASURE\_VALUE field descriptions**

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 X_VALUE	X Value  Coordinate value  <b>NOTE:</b> It is an ADC conversion value, SW need to convert it to fit screen size.
15–12 Reserved	This read-only field is reserved and always has the value 0.
Y_VALUE	Y Value  Y coordinate value, note, it is an ADC conversion value, SW need to convert it to fit screen size

**68.4.5 Interrupt Enable (TSC\_INT\_EN)**

Address: 400E\_0000h base + 40h offset = 400E\_0040h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R									0								
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R				0		IDLE_SW_INT_		EN				0					
W													DETCT_INT_				MEASURE_INT_
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

**TSC\_INT\_EN field descriptions**

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 IDLE_SW_INT_	Idle Software Interrupt Enable  This field indicates whether enable the software return to idle status interrupt. This interrupt is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1.  0 Disable idle software interrupt 1 Enable idle software interrupt

Table continues on the next page...

**TSC\_INT\_EN field descriptions (continued)**

Field	Description
11–5 Reserved	Reserved  This read-only field is reserved and always has the value 0.
4 DETECT_INT_EN	Detect Interrupt Enable  This field indicates whether enable the detect interrupt. This interrupt is generated if there is a touch detect after pre-charge ready.  0 Disable detect interrupt 1 Enable detect interrupt
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE_INT_EN	Measure Interrupt Enable  This field indicates whether enable the measure interrupt. This interrupt is generated after the touch detection which follows measurement.  0 Disable measure interrupt 1 Enable measure interrupt

**68.4.6 Interrupt Signal Enable (TSC\_INT\_SIG\_EN)**

Address: 400E\_0000h base + 50h offset = 400E\_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R									0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R				0				VALID_SIG_EN				0		0		
W				IDLE_SW_SIG_EN								DETECT_SIG_EN		0		MEASURE_SIG_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**TSC\_INT\_SIG\_EN field descriptions**

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**TSC\_INT\_SIG\_EN field descriptions (continued)**

Field	Description
12 IDLE_SW_SIG_EN	Idle Software Signal Enable  This field indicates whether enable the software return to idle status. This signal is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1.  0 Disable idle software signal 1 Enable idle software signal
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 VALID_SIG_EN	Valid Signal Enable  This field indicates whether enable the valid signal. This field generated at the same time with MEASURE_SIG_EN.  0 Disable valid signal 1 Enable valid signal
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 DETECT_SIG_EN	Detect Signal Enable  This field indicates whether enable the detect signal.  0 Disable detect signal 1 Enable detect signal
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE_SIG_EN	Measure Signal Enable  This field indicates whether enable the measure signal.

**68.4.7 Interrupt Status (TSC\_INT\_STATUS)**

Address: 400E\_0000h base + 60h offset = 400E\_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R									0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0			IDLE_SW	0			VALID	0			DETCT	0			MEASURE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**TSC\_INT\_STATUS field descriptions**

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 IDLE_SW	<p>Idle Software</p> <p>This field indicates whether the state machine return to idle status. This signal is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1.</p> <p>0 Haven't return to idle status 1 Already return to idle status</p>
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 VALID	<p>Valid Signal</p> <p>This field indicates whether the measure value is valid. This field generated at the same time with MEASURE_SIG.</p> <p>0 There is no touch detected after measurement, indicates that the measured value is not valid 1 There is touch detection after measurement, indicates that the measure is valid</p>
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 DETECT	<p>Detect Signal</p> <p>This field indicates whether there is a detect signal.</p> <p>0 Does not exist a detect signal 1 Exist detect signal</p>
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE	<p>Measure Signal</p> <p>This field indicates whether there is a measure signal.</p> <p>0 Does not exist a measure signal 1 Exist a measure signal</p>

## 68.4.8 Debug Mode Register (TSC\_DEBUG\_MODE)

Address: 400E\_0000h base + 70h offset = 400E\_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R				0		0					0					
W				DEBUG_EN			ADC_COCO_DISABLE		ADC_COCO_CLEAR		TRIGGER			EXT_HWTS		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R				ADC_COCO									ADC_CONV_VALUE			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**TSC\_DEBUG\_MODE field descriptions**

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DEBUG_EN	<p>Debug Enable</p> <p>The RO registers in debug_mode and debug_mode2 always reflect the latest value and is not controlled by this bit. All RW SW bits are controlled by this bit.</p> <p>0 Enable debug mode 1 Disable debug mode</p>
27 Reserved	This read-only field is reserved and always has the value 0.
26 ADC_COCO_ CLEAR_ DISABLE	<p>ADC COCO Clear Disable</p> <p>This bit could prevent TSC HW generates an ADC COCO clear signal.</p> <p><b>NOTE:</b> This bit does not effect ADC_COCO_CLEAR bit.</p> <p>0 Allow TSC hardware generates ADC COCO clear 1 Prevent TSC from generate ADC COCO clear signal</p> <p>— —</p>
25 ADC_COCO_ CLEAR	<p>ADC Coco Clear</p> <p>Original ADC coco only clear is system read conv result from IPS bus. However, TSC read conv result directly from ADC to lower SW load, so that ADC requires TSC generates a clear signal.</p> <p>0 No ADC COCO clear 1 Set ADC COCO clear</p>
24 TRIGGER	<p>Trigger</p> <p>Hardware trigger signal to ADC</p> <p>0 No hardware trigger signal 1 Hardware trigger signal, the signal must last at least 1 ips clock period</p>
23–21 Reserved	This read-only field is reserved and always has the value 0.
20–16 EXT_HWTS	<p>Hardware Trigger Select Signal</p> <p>Hardware trigger select signal, select which channel to start conversion.</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 ADC_COCO	<p>ADC COCO Signal</p> <p>This signal is generated by ADC.</p>
ADC_CONV_ VALUE	<p>ADC Conversion Value</p> <p>This signal is generated by ADC.</p>

## 68.4.9 Debug Mode Register 2 (TSC\_DEBUG\_MODE2)

Address: 400E\_0000h base + 80h offset = 400E\_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 XPUL_PULL_DOWN	<p>XPUL Wire Pull Down Switch This is a control signal of this XPUL wire pull down switch.</p> <p>0 Close the switch 1 Open up the switch</p>

# Appendix A

## Revision History

The following table provides a revision history for this document.

**Table A-1. Revision History**

Rev. No.	Date	Substantial Changes
0	08/2018	Initial public release.
1	12/2018	Major revision upgrade: updates in several chapters, see "Change summary" in this specific revision for more details.
2	12/2019	Major revision upgrade: updates in several chapters, see "Substantive changes" in this specific revision for more details.
3	07/2021	Major revision upgrade: updates in several chapters, see "Substantive changes" below for more details.

## **Appendix B**

## **Substantive changes for this revision**

Substantive changes for this revision are as follows:

### **B.1 About this Document Revision History**

No substantive changes

### **B.2 Introduction Revision History**

No substantive changes

### **B.3 Memory Maps Revision History**

No substantive changes

### **B.4 Interrupts, DMA Events, and XBAR Assignments Revision History**

- Minor corrections in the tables “CM7 domain interrupt summary” and “XBAR3 Input Assignments”.

### **B.5 DMAMUX Revision History**

- Block guide structure optimized, and added the section “Clocks”.

## B.6 eDMA Revision History

- Block guide optimized: e.g. some changes in the section “Block parts”, added the section “Clocks”, and some edits in the register part.

## B.7 System Security Revision History

No substantive changes

## B.8 System Debug Revision History

- Some corrections: removed “AMBA Trace Bus (ATB)” and “Coresight Embedded Trace Buffer (ETB)” sections.
- Added new sections “Cortex-M7 DAP (CM7DAP)”, “Cross-Trigger Interface (CTI)”, “Timestamp Generator (TSGEN)” and “JTAG-to-SWD change sequence”.

## B.9 System Boot Revision History

- Minor corrections in the tables “FlexSPI Configuration block”, “Serial NOR configuration block” and “Valid DCD address ranges”.
- The table “ROM Clock Setting” and related notes repositioned at the section “Clocks at boot time”.
- Removed the table “IOMUX configuration for SD/MMC”, as the related content is already covered in the table “ROM Bootloader Peripheral PinMux”.
- Editorial updates (e.g. some extra notes added) throughout the chapter.

## B.10 External Signals and Pin Multiplexing Revision History

No substantive changes

## B.11 IOMUXC Revision History

- Block guide structure optimized, minor updates and editorial changes in the register part.

## B.12 GPIO Revision History

- Block guide structure optimized, and some editorial updates.

## B.13 Clock and Power Management Revision History

- Updated the table “Low Power Mode Definition”.

## B.14 CCM Revision History

- Updated the tables “System Clocks, Gating, and Override” and “System Clock Frequency Values”.
- Minor updates and editorial changes in the register part.

## B.15 XTALOSC Revision History

No substantive changes

## B.16 PMU Revision History

No substantive changes

## B.17 GPC Revision History

No substantive changes

## B.18 DCDC Revision History

- Some notes added in the section “Chip-specific DCDC information”.
- Block guide structure optimized.

## B.19 TEMPMON Revision History

No substantive changes

## B.20 SNVS Revision History

- Thorough updates in the whole chapter, and some sections only show up in the Security Reference Manual.

## B.21 SRC Revision History

- Block guide structure optimized.

## B.22 Fusemap Revision History

- Minor updates in the fusemap tables.

## B.23 OCOTP Revision History

- Block guide structure optimized, and minor updates in the register part.

## B.24 External Memory Controllers Revision History

No substantive changes

## B.25 SEMC Revision History

- Block guide fully optimized, also with new sections added: e.g. “Initialization” and “Application Information”.

## B.26 uSDHC Revision History

- Thorough updates in the whole chapter, e.g. in sections “Overview”, “Signals overview”, “Clock generator”, “Application of uSDHC”, and minor updates in the register part.

## B.27 FlexSPI Revision History

- Block guide structure optimized, and minor update in the register part.
- Added new sections, such as “Receiving block diagram” and under the “AHB Memory Map definition” section.
- Updated the table “External Signal List”.

## B.28 Arm Cortex M7 Revision History

- Block guide structure optimized, and added the CM7\_MCM register part.

## B.29 NIC Revision History

No substantive changes

## B.30 OCRAM Revision History

- Block guide structure optimized, no substantial content change.

## B.31 FlexRAM Revision History

- Minor update in the “FlexRAM Clocks” table.

## B.32 AIPSTZ Revision History

- Minor correction (“resource domain” related information is not applicable in this device), no substantial change.

## B.33 Display and Camera Overview Revision History

- Updated the “CMOS Sensor Interface (CSI)” overview section.

## B.34 CSI Revision History

- Block guide structure optimized, and minor update in the register part.

## B.35 eLCDIF Revision History

- Block guide structure optimized.

## B.36 PXP Revision History

- Block guide structure optimized.

## B.37 Audio Overview Revision History

No substantive changes

## B.38 SAI Revision History

- Added the table “SAI MCLK Information”, in the Chip-specific information section.
- Block guide structure optimized.

## B.39 MQS Revision History

- Block guide structure optimized, no substantial content change.

## B.40 SPDIF Revision History

- Block guide structure optimized, no substantial content change.

## B.41 ENET Revision History

- Chapter title corrected as “10/100-Mbps Ethernet MAC (ENET)”.
  - Block guide structure optimized.

## B.42 USB Revision History

No substantive changes

## B.43 USB PHY Revision History

No substantive changes

## B.44 FLEXCAN Revision History

- Minor update in the register part.

## B.45 CANFD/FlexCAN3 Revision History

- Block guide structure optimized.

## B.46 KPP Revision History

- Block guide structure optimized.

## B.47 LPI2C Revision History

- Block guide structure optimized.

## B.48 LP SPI Revision History

- Block guide structure optimized and some contents updated.

## B.49 LPUART Revision History

- Block guide fully optimized.

## B.50 FlexIO Revision History

- Block guide structure optimized and some contents updated, including the register part.
- Added a new section “Keypad Interface”.

## B.51 Timers Overview Revision History

- Updated the sections “Watchdog Timer (WDOG1,2)” and “Watchdog Timer (WDOG3)”.

## B.52 GPT Revision History

- Updated the section “External Signals”.

## B.53 PIT Revision History

- Removed the section “PIT External Signals”.

## B.54 TMR Revision History

- Block guide structure optimized, no substantial content change.

## B.55 eFlexPWM Revision History

- Block guide structure optimized and some contents updated, including the register part.

## B.56 QDC Revision History

- Module name clarified as Quadrature Decoder (QDC).

- Block guide structure optimized, and minor update in the register part.
- Add a new section “Speed Measurement Method”.

## B.57 WDOG1-2 Revision History

No substantive changes

## B.58 RTWDOG/WDOG3 Revision History

- Update the section “Chip-specific RTWDOG information”.
- Block guide structure optimized and some contents updated, including the register part.
- Added a new section “Disable Watchdog after Reset”.

## B.59 EWM Revision History

- Block guide structure optimized, no substantial content change.

## B.60 On Chip Cross Triggers Overview Revision History

No substantive changes

## B.61 XBAR A Revision History

- Block guide structure optimized, no substantial content change.

## B.62 XBAR B Revision History

- Block guide structure optimized, no substantial content change.

## B.63 AOI Revision History

- Block guide structure optimized, no substantial content change.

## B.64 Analog Overview Revision History

No substantive changes

## B.65 ACMP Revision History

No substantive changes

## B.66 ADC Revision History

- Updated the COCOn bitfields in “Status register for HW triggers (ADCx\_HS)”.

## B.67 ADC\_ETC Revision History

- Block guide fully optimized, also with new sections added: e.g. “Initialization” and “Application Information”, and thorough editorial updates in the register part.

## B.68 TSC Revision History

No substantive changes

**Limited warranty and liability** — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors. In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

**Security** — Customer understands that all NXP products may be subject to unidentified or documented vulnerabilities. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

**Right to make changes** — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

**Suitability for use** — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

**Applications** — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

**Export control** — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

**Translations** — A non-English (translated) version of a document is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.
